(54) Title: DISPLAY LIST MANAGEMENT MECHANISM FOR REAL-TIME CONTROL OF BY-THE-LINE MODIFIABLE VIDEO DISPLAY SYSTEM

(57) Abstract

The invention provides a method and apparatus (100) for managing color modification of a raster based image on a real time, line-by-line basis and for managing real-time of new imagery into buffers whose data is displayable.

DISPLAY LIST MANAGEMENT MECHANISM FOR REAL-TIME  
CONTROL OF BY-THE-LINE MODIFIABLE  
VIDEO DISPLAY SYSTEM

5

BACKGROUND

10 1. Field of the Invention

The invention relates generally to digital image processing and the display of digitally generated images. The invention relates more specifically to the problem of creating raster-based, high-resolution  
15 animated images in real time, where the mechanism for generating each raster line is modifiable on a by-the-line or on a by-a-group of lines basis.

2a. Copyright Claims to Disclosed Code

A portion of the disclosure of this patent  
20 document contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or the patent disclosure as it appears in the U.S. Patent and Trademark Office patent  
25 file or records, but otherwise reserves all copyright rights whatsoever.

In particular, this application includes C  
language source-code listings of a variety of computer  
program modules. These modules can be implemented by  
30 way of a computer program, microcode, placed in a ROM chip, on a magnetic or optical storage medium, and so forth. The function of these modules can also be implemented at least in part by way of combinatorial logic. Since implementations of the modules which are

- 2 -

deemed to be "computer programs" are protectable under copyright law, copyrights not otherwise waived above in said modules are reserved. This reservation includes the right to reproduce the modules in the form of machine-executable computer programs.

2b. Cross Reference to Related Applications

This application is related to:

PCT Patent Application Serial No. PCT/US92/09342, entitled RESOLUTION ENHANCEMENT FOR VIDEO DISPLAY USING MULTI-LINE INTERPOLATION, by inventors Mical et al., filed November 2, 1992, Attorney Docket No. MDIO3050, and also to U.S. Patent Application Serial No. 07/970,287, bearing the same title, same inventors and also filed November 2, 1992;

PCT Patent Application Serial No. PCT/US92/09349, entitled AUDIO/VIDEO COMPUTER ARCHITECTURE, by inventors Mical et al., filed November 2, 1992, Attorney Docket No. MDIO4222, and also to U.S. Patent Application Serial No. 07/970,308, bearing the same title, same inventors and also filed November 2, 1992;

filed November 2, 1992, Attorney Docket No. MDIO4250,  
and also to U.S. Patent Application Serial No.  
07/969,994, bearing the same title, same inventors and  
also filed November 2, 1992;

15 PCT Patent Application Serial No. PCT/US92/09467,  
entitled IMPROVED METHOD AND APPARATUS FOR PROCESSING  
IMAGE DATA, by inventors Mical et al., filed November  
2, 1992, Attorney Docket No. MDIO4230, and also to  
U.S. Patent Application Serial No. 07/970,083, bearing  
20 the same title, same inventors and also filed November  
2, 1992; and

PCT Patent Application Serial No. PCT/US92/09384,  
entitled PLAYER BUS APPARATUS AND METHOD, by inventors  
Needle et al., filed November 2, 1992, Attorney Docket  
25 No. MDIO4270, and also to U.S. Patent Application  
Serial No. 07/970,151, bearing the same title, same  
inventors and also filed November 2, 1992.

The related patent applications are all commonly  
assigned with the present application and are all  
30 incorporated herein by reference in their entirety.

The present application is to be considered a  
continuation-in-part of one or more of the above  
cited, co-pending applications, including at least one  
of: U.S. Patent Application Serial No. 07/970,287,  
35 filed November 2, 1992 and entitled RESOLUTION

- 4 -

ENHANCEMENT FOR VIDEO DISPLAY USING MULTI-LINE INTERPOLATION; U.S. Patent Application Serial No. 07/969,994, filed November 2, 1992 and entitled METHOD AND APPARATUS FOR UPDATING A CLUT DURING HORIZONTAL  
5 BLANKING; and U.S. Patent Application Serial No. 07/970,289, filed November 2, 1992 and entitled SPRYTE RENDERING SYSTEM WITH IMPROVED CORNER CALCULATING ENGINE AND IMPROVED POLYGON-PAINT ENGINE.

### 3. Description of the Related Art

10 In recent years, the presentation and pre-presentation processing of visual imagery has shifted from what was primarily an analog electronic format to an essentially digital format.

15 Unique problems come to play in the digital processing of image data and the display of such image data. The more prominent problems include providing adequate storage capacity for digital image data and maintaining acceptable data throughput rates while using hardware of relatively low cost. In addition,  
20 there is the problem of creating a sense of realism in digitally generated imagery, particularly in animated imagery.

The visual realism of imagery generated by digital video game systems, simulators and the like  
25 can be enhanced by providing special effects such as moving sprites, real-time changes in shadowing and/or highlighting, smoothing of contours and so forth.

30 Visual realism can be further enhanced by increasing the apparent resolution of a displayed image so that it has a smooth photography-like quality rather than a grainy disjointed-blocks appearance of the type found in low-resolution computer-produced graphics of earlier years.

- 5 -

Visual realism can be even further enhanced by increasing the total number of different colors and/or shades in each displayed frame of an image so that, in regions where colors and/or shades are to change in a smooth continuum by subtle degrees of hue/intensity, the observer perceives such a smooth photography-like variation of hue/intensity rather than a stark and grainy jump from one discrete color/shade to another. Glaring changes of color/shade are part of the reason that computer-produced graphics of earlier years had a jagged appearance rather than a naturally smooth one.

Although bit-mapped computer images originate as a matrix of discrete lit or unlit pixels, the human eye can be fooled into perceiving an image having the desired photography-like continuity if the displayed matrix of independently-shaded (and/or independently colored) pixels has dimensions of approximately 500-by-500 pixels or better at the point of display and a large variety of colors and/or shades on the order of roughly 24 bits-per-pixel or better.

The VGA graphics standard, which is used in many present-day low-cost computer systems, approximates this effect with a display matrix having dimensions of 640-by-480 pixels. However, conventional low-cost VGA graphic systems suffer from a limited per-frame palette of available colors and/or shades.

Standard NTSC broadcast television systems also approximate the continuity mimicking effect by using interlaced fields with 525 lines per pair of fields and a horizontal scan bandwidth (analog) that is equivalent to approximately 500 RGB colored dots per line.

More advanced graphic display standards such as Super-VGA and High Definition Television (HDTV) rely

- 6 -

on much higher resolutions, 1024-by-786 pixels for example. It is expected that display standards with even higher resolution numbers (e.g., 2048-by-2048) will emerge in the future. It is expected that the number of bits per displayed pixel will similarly increase in the future.

As resolutions increase, and a wider variety of colors/shades per frame is sought, the problem of providing adequate storage capacity for the corresponding digital image data becomes more acute. The problem of providing sufficient data processing throughput rates also becomes more acute. This is particularly so if an additional constraint is imposed of keeping hardware costs within acceptable price versus performance range.

A display with 640-by-480 independent pixels (307,200 pixels total) calls for a video-speed frame buffer having at least 19 address bits or a corresponding  $2^{19}$  independently-addressable data words (= 512K words), where each data word stores a binary code representing the shading and/or color of an individual pixel. Each doubling of display resolution, say from 640-by-480 pixels to 1280-by-960 pixels, calls for a four-fold increase in the storage capacity of the frame buffer. Each doubling of per-pixel color/shade variation, say from 8 bits-per-pixel to 16 bits-per-pixel, calls for an additional two-fold increase in storage capacity. This means that a system starting with a display of 8 bits-per-pixel and 640-by-480 independent pixels per screen would conventionally require a memory increase from 512K bytes to 4MB (four Megabytes) as a result of doubling both the number of pixels per row and column and the number of bits-per-pixel. And in cases where parts or all of the resultant 1280-by-960 display field have to

- 7 -

be modified in real-time (to create a sense of animation), the eight-fold increase of storage capacity calls for a corresponding eight-fold increase in data processing bandwidth (image bits processed per second) as compared to what was needed for processing the original, 8 bits-per-pixel, 640-by-480 pixels field.

The benefit versus cost ratio incurred by meeting demands for more storage capacity and faster processing speed has to be questioned at some point. Perhaps a given increase in performance is not worth the increase in system cost. On the other hand, it might be possible to create a perception of improved performance without suffering a concomitant burden of significantly higher cost.

Such an objective can be realized by using a High-performance, Inexpensive, Image-Rendering system (HI-IR system) such as disclosed in the above cited set of co-related patent applications. In particular, part of the low-cost and high-performance of the HI-IR system is owed to the use, in a display-defining path of the system, of a Color LookUp Table (CLUT) whose contents are modifiable on a by-the-line basis. Details of this CLUT system may be found in the above-cited PCT Patent Application Serial No. PCT/US92/09460, entitled METHOD AND APPARATUS FOR UPDATING A CLUT DURING HORIZONTAL BLANKING, by inventors Mical et al., filed November 2, 1992.

Another part of the low-cost and high-performance of the HI-IR system is owed to the use, in the display-defining path of the system, of a subposition-weighted Interpolator whose subposition weights are modifiable on a by-the-pixel basis and whose mode of operation (horizontal-interpolation on/off and

- 8 -

vertical-interpolation on/off) is modifiable on a by-the-line or by-the-frame basis.

Yet another part of the low-cost and high-performance of the HI-IR system is owed to the use, in the display-defining path of the system, of a slip-stream mechanism in which "background" pixels can be replaced or not, on a modifiable by-the-line basis, with so-called externally-provided slipstream video data to create a picture-in-picture or another like effect. A description of this slipstream process may be found in the above-cited PCT Patent Application Serial No. PCT/US92/09349, entitled AUDIO/VIDEO COMPUTER ARCHITECTURE, by inventors Mical et al.

Still another part of the low-cost and high-performance of the HI-IR system is owed to the use, in a bitmap-defining portion of the system, of a unique set of one or more "spryte" rendering engines (also called cel animating engines) for executing a list of bitmap modifications stored in a queue. A description of this mechanism may be found in the above cited PCT Patent Application Serial No. PCT/US92/09350, entitled METHOD FOR CONTROLLING A SPRYTE RENDERING PROCESSOR, and also PCT Patent Application Serial No. PCT/US92/09462, entitled SPRYTE RENDERING SYSTEM WITH IMPROVED CORNER CALCULATING ENGINE AND IMPROVED POLYGON-PAINT ENGINE.

The rich assortment of capabilities that are made possible by these and other mechanisms of the HI-IR system provide benefits on the one hand, but create a new set of problems on the other hand.

In particular, it becomes a problem to manage and coordinate attempts by one or more application programs to alter the configuration of the display-defining path of the HI-IR system, or to change the operations of the spryte-rendering portion of the

- 9 -

HI-IR system. Each operational change that is made either to the display-defining path of the HI-IR system, or to the spryte-rendering portion of the HI-IR system, can result in desired-beneficial changes to what is shown on the display monitor or it can just as easily produce undesired-detrimental changes to what is shown on the display monitor.

The desired-beneficial changes are, of course, no problem. Examples include the creation of a photography-quality background scene over which animated "sprytes" move.

The undesired-detrimental changes can give nontechnical users of the machine a wrong impression of what is happening to their machine. Such users may come to believe that something has become permanently damaged within their machine (even though this is not true) and the users may then come to form a poor opinion of the machine's performance capabilities. It is preferable to give nontechnical users an impression that the machine is "robust" and can perform even under adverse conditions where an ill-behaved application program is installed in the machine.

There are some portions of the display-defining path of the HI-IR system, for example, that should be "configured" one time only, during the power-up/reset phase of machine operation (initialization phase). An example is the setting of a video-display driver within the system to an NTSC television drive mode or a PAL television drive mode. An ill-behaved module within an application program might inadvertently load a new configuration into the system after power-up/reset and thereby cause the entire display to show out-of-synch noise or "garbage". It may not be possible to fix this problem other than by shutting power off and restarting the machine. This type of

- 10 -

"fix" is undesirable because it gives nontechnical users a notion that their machine is not as "robust" as they would like it to be. Manufacturers wish to continuously leave consumers with an impression that the machine they purchased is "robust" and is able to continue functioning in some minimal way even if loaded with an ill-behaved application programs.

On the other hand, manufacturers wish to make machines that are easily reconfigured to meet the requirements of specific markets. Systems sold in the United States are preferably configured, for example, to conform to the NTSC television standard while systems sold in Europe are preferably configured to conform to the PAL television standard.

A first presented problem is therefore how to permit easy reconfiguration of machines to conform with standards of different markets and yet at the same time avoid the appearance of less than robust, machine performance even in the case where an ill-behaved application program manages to enter the system.

Another problem relates to making sure that certain post-initialization reconfigurations of the display-defining path of the HI-IR system are carried in a timely manner and coordinated with operations of the spryte rendering engines. Some operations of the display-defining path of the HI-IR system and of the spryte rendering engines are preferably modified or "re-configured" on a by-the-frame basis, or on a by-the-line basis. These modifications/reconfigurations should be coordinated with real-time events of the display-defining path of the system such as the actuation of the horizontal synch and vertical synch pulses of the video generating system.

- 11 -

In some situations, it is undesirable to let reconfiguration of a displayed image occur in the middle of an active scan line. This might create a clearly visible and annoying "tear" artifact or other disturbance in the displayed imagery. Ideally, reconfiguration should occur during the vertical blanking or horizontal blanking periods of the system so as to avoid the image-tearing problem.

On the other hand, the performance speed of real-time games or simulations might suffer if one always had to wait for the next horizontal or vertical blanking period each time a change was to be made. Some kinds of imagery changes can be made without creating a noticeable disturbance within the displayed image while others cannot. A flexible mechanism is needed for allowing both kinds of changes.

Another problem presented here is therefore, how to efficiently organize and prioritize the execution of real-time image and modality changes on a by-the-line or by-the-frame basis. A method is needed for coordinating and prioritizing changes to be made to the display-defining path of the HI-IR system and changes made by the spryte-rendering portion of the system.

25

#### SUMMARY OF THE INVENTION

The invention overcomes the above-mentioned problems by providing a set of graphics management primitives for coordinating reconfigurations of a system having a reconfigurable display-defining path.

A first aspect of the graphics management primitives involves providing a proofer that receives proposed display structures from application programs,

- 12 -

proofs them for inconsistencies and filters out attempts to reconfigure a digital-to-video translating portion of the system after a system initialization phase completes.

5           A second aspect of the graphics management primitives involves establishing a master VDL (Video Data List) that allows for efficient execution of color palette changes and/or execution of cel animation activities.

10           A third aspect of the graphics management primitives involves generating support data structures in memory for supporting general purpose color palette changes and/or execution of cel animation activities.

#### BRIEF DESCRIPTION OF THE DRAWINGS

15           The below detailed description makes reference to the accompanying drawings, in which:

          Figures 1A and 1B form a block diagram of a High-performance, Inexpensive, Image-Rendering system (HI-IR system) in accordance with the invention that  
20 includes a Video Display List (VDL) management subsystem;

          Figure 2 diagrams a "simple" Displayable, Animateable, Image Buffer (DAIB) structure;

          Figure 3 diagrams a "split, double-buffered" DAIB  
25 structure.

#### DETAILED DESCRIPTION

          Referring to the combination of Figures 1A and 1B, a block diagram of an image processing and display system 100 in accordance with the invention is shown.

30           A key feature of system 100 is that it is relatively low in cost and yet it provides mechanisms for handling complex image scenes in real time and displaying them such that they appear to have

- 13 -

relatively high resolution and a wide variety of colors and/or shades per displayed frame.

This feature is made possible by including a image-enhancing and display subsystem 150 (Fig. 1B) on one or a few integrated circuit (IC) chips within the system 100. Included within the image-enhancing and display subsystem 150 are a set of user-programmable Color LookUp Table modules (CLUT's) 451, 452, a hardwired pseudo-linear CLUT 484 and a user-programmable resolution-enhancing interpolator 459. The operations of these and other components of subsystem 150 are best understood by first considering the video processing operations of system 100 in an overview sense.

Figures 1A and 1B join, one above the next, to provide a block diagram of the system 100. Except where otherwise stated, all or most parts of system 100 are implemented on a single printed circuit board 99 and the circuit components are defined within one or a plurality of integrated circuit (IC) chips mounted to the board 99. Except where otherwise stated, all or most of the circuitry is implemented in CMOS (complementary metal-oxide-semiconductor) technology using 0.9 micron or narrower line widths. An off-board power supply (not shown) delivers electrical power to the board 99.

Referring first to Fig. 1B, system 100 includes a video display driver 105 that is operatively coupled to a video display unit 160 such as an NTSC standard television monitor or a PAL standard television monitor or a 640-by-480 VGA monitor. The monitor 160 is used for displaying high-resolution animated images 165. Video display driver 105 has a front-end, frame clocking portion 105a and a backend, digital-to-video translating portion 105b. The front-end, frame

- 14 -

clocking portion 105a generates frame synchronization signals 106 such as a vertical synch pulse (V-synch) and a horizontal synch pulse (H-synch). The backend translating portion 105b can be a digital-to-NTSC translator or a digital-to-PAL translator or a digital-to-VGA translator or a digital-to-other format translator. Preferably, the video display driver 105 is a software-configurable device such as a Philips 7199™ video encoder. Such a device responds to configuration instructions downloaded into it so that the same device is useable in either an NTSC environment or a PAL environment or another video-standard environment.

Referring to Fig. 1A, system 100 further includes a real-time image-data processing unit (IPU) 109, a general purpose central-processing unit (CPU) 110, and a multi-port memory unit 120.

The memory unit 120 includes a video-speed random-access memory subunit (VRAM) 120'. It can also include slower speed DRAM or other random access data storage means. Instructions and/or image data are loadable into the memory unit 120 from a variety of sources, including but not limited to floppy or hard disk drives, a CD-ROM drive, a silicon ROM (read-only-memory) device, a cable headend, a wireless broadcast receiver, a telephone modem, etc. Paths 118 and 119 depict in a general sense the respective download into memory unit 120 of instructions and image data. The downloaded image data can be in compressed or decompressed format. Compressed image data is temporarily stored in a compressed image buffer 116 of memory unit 120 and expanded into decompressed format on an as needed basis. Such decompression is depicted in a general sense by transfer path 117. Displayable image data, such as that provided in a below-described

- 15 -

video image band 125.0 is maintained in a decompressed format.

Memory unit 120 is functionally split into dual, independently-addressable storage banks, 120a and 120b, which banks are occasionally referred to herein respectively as bank-A and bank-B. The split VRAM portions are similarly referenced as banks 120'a and 120'b. The address inputs to the storage banks, 120a and 120b, of memory unit 120 are respectively referenced as 121a and 121b, and the address signals carried thereon are respectively referenced as  $A_a$  and  $A_b$ .

Noncompressed, displayable, bit-mapped image data is preferably stored within memory unit 120 so that even numbered image lines reside in a first of the memory banks (e.g., 120a) and odd numbered image lines reside in the second of the memory banks (e.g., 120b). For purposes of a below-described interpolation process, a first image line in a first of the banks is referenced as a "current" line and a corresponding second image line in a second of the banks is referenced as a "previous" line. The designation is swappable. An image line of either bank can be designated at different times as being both "current" and "previous". In the example of Fig. 1A, VRAM bank 120'a is shown holding a "previous" image line while VRAM bank 120'b is shown holding a "current" image line.

Each of memory banks 120a, 120b has a first bi-directional, general purpose data port (referenced respectively and individually as 122a, 122b) and a second, video-rate data port (referenced as 123a, 123b). Collectively, the general purpose data port of the memory unit 120 is referred to as the D-bus port

- 16 -

122 while the video-rate data port is referred to as the S-bus port 123.

5 The first set of bidirectional data ports 122a, 122b (collectively referenced to as 122) connect to the IPU 109, to the CPU 110 and to a dual-output memory-address driver/DMA controller (MAD/DMA) 115 by way of a data/control bus (DCB) 107. The data/control bus (DCB) 107 also carries control signals between the various units.

10 The second set of memory data ports (video-output ports) 123a, 123b of the memory unit 120 connect to the above-mentioned, image-enhancing and display subsystem 150 by way of a so-called S-bus 123.

15 The dual-output memory-address driver/DMA controller (MAD/DMA) 115 is responsible for supplying address and control signals (A and C) to the independently-addressable storage banks, 120a and 120b, of memory unit 120 on a real-time, prioritized basis. As will be understood shortly, some of the address signals ( $A_a$ ,  $A_b$ ) need to or can be timely delivered during a horizontal-blanking period (H-BLANK) and others of the address signals need to or can be timely delivered during a horizontal active-scan period (H-SCAN). Yet others of the address signals need to or can be timely delivered during a vertical-blanking period (V-BLANK). And yet others of the address signals need to or can be timely delivered at the start of a vertical-active period (at V-sync or within the first 21 NTSC scan lines).

20  
25  
30 The dual-output memory-address driver/DMA controller (MAD/DMA) 115 performs this function in accordance with a supplied list of ordered commands stored in a "Master" set of Video Line(s) Control Blocks that is stored in the video random-access memory subunit (VRAM) 120' of memory unit 120. The  
35

- 17 -

Master set of VLCB's is referenced as 215. The contents of the Master set of VLCB's 215 defines what will be seen on the monitor screen at a given moment, and hence the master set 215 is also at times referred to herein as the "master screen definition" 215 or the  
5 currently active "Video Display List" (VDL) 215.

The CPU 110 or another memory altering means can define one or more VDL's within memory unit 120 and shift them around as desired between VRAM 120' and other sections of system memory. The CPU 110 sets a  
10 register within the memory-address driver/DMA controller (MAD/DMA) 115 to point to the VRAM address where the currently active "Video Display List" (VDL) 215 begins. Thereafter, the memory-address driver/DMA  
15 controller (MAD/DMA) 115 fetches and executes commands from the Master set of VLCB's 215 in timed response to the frame synchronization signals 106 supplied from the display-drive frame-clocking portion 105a. The portion of the memory-address driver/DMA controller  
20 (MAD/DMA) 115 that provides this function is occasionally referred to herein as the VDLE (Video Display List Engine) 115'.

Each individual VLCB (Video Line(s) Control Block) within the Master set of VLCB's 215 is  
25 individually referenced with a decimated number such as 215.0, 215.1, 215.2, etc. For each displayed screen, the first fetched and executed control block is VLCB number 215.0 which is also referred to as VDL section 215.0 (Video-control Data List section number  
30 215.0). The remaining VLCB's, 215.1, 215.2 may or may not be fetched and executed by the VDLE 115' depending on the contents of the first VLCB 215.0. The contents of each VLCB 215.0, 215.1, ..., 215.i and the corresponding functions will be more fully described  
35 below.

- 18 -

As already mentioned, the front-end, frame clocking portion 105a of the video display driver 105 generates a plurality of frame synchronization signals 106. These include: (a) a low-resolution video pixel (LPx) clock for indexing through pixels of a low-resolution video image band 125.0 stored in memory unit 120; (b) a V-synch pulse for identifying the start of a video frame (or field); (c) an H-synch pulse for identifying the start of a horizontal scan line; (d) an H-BLANK pulse for identifying the duration of a horizontal-blanking period; and (e) a V-BLANK pulse for identifying the duration of a vertical-blanking period.

In one embodiment, the image data processing unit (IPU) 109 is driven by a processor clock generator 102 (50.097896 MHz divided by one or two) operating in synchronism with, but at a higher frequency than the low-resolution pixel (LPx) clock generator 108 (12.2727 MHz) that drives the frame-clocking portion 105a of the display-drive. The CPU 110 can be a RISC type 25MHz or 50MHz ARM610 microprocessor available from Advanced RISC Machines Limited of Cambridge, U.K. A plurality of spryte-rendering engines 109a,b (not shown in detail) are provided within the IPU 109 for writing in real-time to image containing areas (e.g., 125.0) of memory unit 120 and thereby creating real-time, animated image renditions. The spryte-rendering activities of the spryte-rendering engines 109a,b can be made to follow a linked list which orders the rendering operations of the engines and even prioritizes some renditions to take place more often than others.

In a system initialization phase of operations, display drive configuration instructions may be downloaded into the video display driver 105 (Fig. 1B)

- 19 -

by way of S-bus 123 and a configuration routing module (AMYCTL module) 156 and a routing multiplexer 157. In an alternate embodiment, the configuration of the video display driver 105 is hardwired. Once the frame synchronization signals 106 are set to proper speeds and timings, and are up and running, the CPU 110 sets the register (not shown) within the memory-address driver/DMA controller (MAD/DMA) 115 that points to the start of the currently active "Video Display List" (VDL) 215, and the VDLE 115' portion of the memory-address driver/DMA controller (MAD/DMA) 115 begins to fetch and execute the display control command stored in the Master VDL 215. The screen display of the video display unit 160 is refreshed accordingly.

At the same time that a screen image 165 is being repeatedly sent to video display unit 160 by the VDLE 115', the IPU 109 and/or CPU 110 can begin to access binary-coded data stored within the memory unit 120 and to modify the stored data at a sufficiently high-rate of speed to create an illusion for an observer that real-time animation is occurring in the high-resolution image 165 (640-by-480 pixels, 24 bits-per-pixel) that is then being displayed on video display unit 160. In many instances, the observer (not shown) will be interacting with the animated image 165 by operating buttons or a joystick or other input means on a control panel (not shown) that feeds back signals representing the observer's real-time responses to the image data processing unit (IPU) 109 and/or the CPU 110 and the latter units will react accordingly in real-time.

The IPU 109 and CPU 110 are operatively coupled to the memory unit 120 such that they (IPU 109, CPU 110) have read/write access to various control and image data structures stored within memory unit 120

- 20 -

either on a cycle-steal basis or on an independent access basis. For purposes of the present discussion, the internal structures of IPU 109 and CPU 110 are immaterial. Any means for loading and modifying the contents of memory unit 120 at sufficient speed to produce an animated low-resolution image data structure therein will do. The important point to note is that the image 165 appearing on video display unit 160 is a function of time-shared activities of the IPU/CPU 109/110 and the Video Display List Engine 115'.

The image 165 that is rendered on monitor 160 is defined in part by bitmap data stored in one or more screen-band buffers (e.g., 125.0) within memory unit 120. Each screen-band buffer contains one or more lines of bit-mapped image data. Screen-bands can be woven together in threaded list style to define a full "screen" as will be explained below, or a single screen-band (a "simple" panel) can be defined such that the one band holds the bit-mapped image of an entire screen (e.g., a full set of 240 low-resolution lines).

Major animation changes are preferably performed on a double-buffered screen basis where the contents of a first screen buffer are displayed while an image modifying engine (the cel or "spritte" engines 109a,b) operates on the bit-map of a hidden, second screen buffer. Then the screen buffers are swapped so that the previously hidden second buffer becomes the displayed buffer and the previously displayed first buffer becomes the buffer whose contents are next modified in the background by the image modifying engine.

Each line in a screen-band buffer (e.g., 125.0) contains a block of low-resolution "halfwords", where

- 21 -

each halfword (16 bits) represents a pixel of the corresponding low-resolution line. The line whose contents are being instantaneously used for generating a display line is referred to as a "current" low-resolution line, and for purposes of interpolation, it is associated with a "previous" low-resolution line.

Memory unit 120 outputs two streams of pixel-defining "halfwords,"  $Px(LR_0)$  and  $Px(LR_1)$ , on respective video-rate output buses 123a and 123b to the image-enhancing and display subsystem 150 in response to specific ones of the bank-address signals,  $A_a$  and  $A_b$  supplied by the memory-address driver (MAD/DMA) 115. A selectable one of these streams defines the "current" line and the other defines the "previous" line. Each 16-bit halfword contains color/shade defining subfields for a corresponding pixel. The make-up of each 16 bit halfword depends on which of a plurality of display modes is active.

In one mode of operation (the 1/555 mode), 5 of the bits of the 16-bit halfword define a red (R) value, 5 of the bits define a green (G) value, 5 of the bits define a blue (B) value, and the last bit (a "subposition weighting" bit) defines a weight value, 0 or 1, to be used by the interpolator 459.

In second mode of operation (the 1/554/1 mode), 5 of the bits define a red (R) value, 5 of the bits define a green (G) value, 4 of the bits define a blue (B) value, and the last 2 bits ("subposition weighting" bits) define a weight value, 0 to 3, to be used by the interpolator 459.

In a third mode of operation (the P/555 mode), 5 of the bits define a red (R) value, 5 of the bits define a green (G) value, 5 of the bits define a blue (B) value, and the last bit (the P or "soft-versus-hard palette select" bit) defines whether the user-

- 22 -

programmable Color LookUp Table modules (CLUT's) 451, 452 or the hardwired pseudo-linear CLUT 484 will be used for performing color code expansion (from 5-bits per color to 8-bits per color) in the image-enhancing and display subsystem 150.

In fourth mode of operation (the P/554/1 mode), 5 of the bits define a red (R) value, 5 of the bits define a green (G) value, 4 of the bits define a blue (B) value, 1 of the bits (a "subposition weighting" bit) defines a weight value, 0 or 1, to be used by the interpolator 459, and the last 1 bit (the P or "soft-versus-hard palette select" bit) defines whether the user-programmable Color LookUp Table modules (CLUT's) 451, 452 or the hardwired pseudo-linear CLUT 484 will be used for performing color code expansion.

The image-enhancing and display subsystem 150 includes a stream routing unit 151 for selectively transposing the  $P_x(LR_0)$  and  $P_x(LR_1)$  signals, in response to a supplied "cross-over" signal, XC, so that one of these video stream streams becomes defined as being the "current line" and the other comes to be defined as the "previous line". When the soft (user-programmable) Color LookUp Table modules (CLUT's) 451, 452 are used, one module holds the conversion palette for the current line and the other for the previous line. Each time the display of a new line completes, the contents of the "current" CLUT module 451 are copied to the "previous" CLUT module 452.

Each CLUT module has three independent CLUT's, an R-CLUT, a G-CLUT, and a B-CLUT. Each of the R,G,B CLUT's has 5 address input lines and 8 data output lines. Thus each CLUT module, 451 or 452, converts a 15-bit wide color code into a 24-bit wide color code.

In the illustrated example, 451 is the C-CLUT module and 452 is the P-CLUT module. The interpolator

- 23 -

459 tends to produce different results depending on which pixel stream is defined as "current" and which as "previous". The cross-over signal, XC, that is applied to the stream routing unit 151 designates  
5 which of the parallel streams from the video-rate output buses 123a and 123b of memory unit 120 will pass through the C-CLUT module 451 or the P-CLUT module 452 and respectively function as "current" or as "previous".

10 If the hardwired pseudo-linear CLUT 484 is to be used for color expansion instead of the user-programmable CLUT modules 451, 452, the stream routing unit 151 routes both the pixel streams of the video-rate memory output buses 123a, 123b through the  
15 hardwired pseudo-linear CLUT module 484. A substantially same color expansion algorithm is then applied to both streams. In one mode of operation for unit 484, the 5 bits of each of the RGB colors are shifted left by 3 bit positions and the less  
20 significant bits of the resulting 8-bit wide values are set to zero. In a second mode, a pseudo-random 3-bit pattern is written into the less significant bits of the resulting 8-bit wide values.

The three stream routing output lines of stream-  
25 routing unit 151 are respectively labeled C-line, H-line and P-line, and are respectively connected to the inputs of the C-CLUT 451, the hardwired pseudo-linear CLUT 484 and the P-CLUT 452. A zero detector 351 has inputs coupled to the 15-bit wide signals  
30 moving down the C-line, the H-line and the P-line. The zero detector 351 further has control outputs coupled to the C-CLUT 451 and to the P-CLUT 452 and also to a control decoder 154 that controls the operation of a below-described multiplexer 152.

- 24 -

In one mode of operation, an all-zero color code (RGB=000) is used to designate a special "background" pixel color. Each of the C-CLUT 451 and the P-CLUT 452 can have its own unique, software-defined background color. In a first submode of operation, each zero-value pixel code (RGB=000) is replaced by the expanded background color code of the corresponding CLUT module 451 or 452. In a second submode of operation, each background pixel is replaced by a 24-bit wide "slipstream" pixel. An external video source (not shown) provides the 24-bit wide slipstream 153 of pixel data at a "GENLOCKED" rate. (Due to chip pinout limitations, the slipstream signal 153 comes in by way of the S-bus 123, time-multiplexed with other S-bus signals and thus it is shown to be sourced by a dashed line from the S-bus 123.) If the second submode (slipstream override mode) is active, each "background" pixel is replaced by a corresponding slipstream pixel. This makes the background pixel appear to have a "transparent" color because the slipstream image shines through.

A second stream routing unit 152 (multiplexer 152) receives the 24-bit wide streams respectively output from the C-CLUT 451, the P-CLUT 452, the hard CLUT 484 and the slipstream source line 153. The second stream routing unit (multiplexer) 152 forwards a selected subset of these received streams to the interpolator unit 459 as a 24-bit wide C-stream and a 24-bit wide P-stream ("current" and "previous" streams). The output of zero detector 351 connects to a control decoder 154 that drives the control port of the second stream routing unit (multiplexer) 152. The zero detector output is used for dynamically replacing background pixels with corresponding slipstream pixels when the slip/stream override mode (EnS/S) is active.

- 25 -

(See Bit 20 of the below defined first DMA control word 311.) The interpolator 459 can be used to smooth sharp differentiations at a boundary between a slipstream image and a VRAM-supplied image.

5 Another control signal which is applied to multiplexer 152 and appropriately decoded by control decoder 154, is a palette select (PalSel) signal which is sometimes referred to also as the "cluster select" signal. This signal selects on a line-by-line basis  
10 one or the other of the user-programmable CLUT modules 451, 452 or the hardwired CLUT module 484 as the means to be used for color code expansion (from 5-bits per color to 8-bits per color). There is also a P/ signal supplied from a subposition extraction unit 155 to the  
15 control decoder 154 for dynamically selecting on a pixel-by-pixel basis one or the other of the user-programmable CLUT modules 451, 452 or the hardwired CLUT module 484 as the means to be used for color code expansion. The latter operation is used in the  
20 P/554/1 and P/555 modes.

Interpolator 459 receives the 24-bit wide C-stream and P-stream video signals from multiplexer 152 in accordance with the selection criteria applied to multiplexer 152. Depending on whether one or both  
25 of a horizontal interpolation mode (HIon) and a vertical interpolation mode (VIon) are active or not, the interpolator can enhance the resolution in the horizontal and/or vertical direction of the received signals. In one mode, the interpolator 459 converts  
30 a 320 by 240 pixels, low-resolution image into a 640 by 480 pixels, high-resolution image. The interpolation operations of interpolator 459 are responsive to a set of supplied weighting bits (which are also referred to as subposition bits, or C-SUB and  
35 P-SUB bits). These bits, C-SUB and P-SUB, can be

- 26 -

fixed or extracted from the S-bus 123. A subposition extraction unit 155 is provided for, in one mode, extracting the subposition bits from the S-bus 123, time delaying them, and supplying them to interpolator 459 in phase with the arriving C-stream and P-stream signals.

The subposition extraction unit 155 is responsive to control signals supplied from a set of VDL control registers 158. The VDL control registers 158 are set or reset in accordance with VDL data downloaded from the Master set of VLCB's 215. The VDL control registers 158 are also used for establishing the operational modes of other parts of the image-enhancing and display subsystem 150 as will be detailed shortly.

The output of interpolator 459 is a 24-bit wide interpolated signal 460 which is next fed to multiplexer 157. Among other functions, multiplexer 157 converts each instance of the 24-bit wide interpolated signal 460 into two 12-bit wide chip-output signals 462. This is done in order to minimize chip-pinout counts. Chip-output signals 462 are then directed to the digital-to-video translating portion 105b.

A digit-to-analog converter (D/A) is included in the backend portion 105b of the display driver for converting the output of interpolator 459 from digital format to analog format. In one embodiment, the D/A converter outputs NTSC formatted analog video to an NTSC compatible monitor 160.

In addition to, or instead of, being directed to the digital-to-video translating portion 105b, the chip-output signals (CLIO output signals) 462 can be directed to a digital signal storage/processing means 170 which stores the chip-output signals 462 and/or

- 27 -

digitally processes them (e.g., by scaling the size of the image data contained therein) and thereafter forwards the stored/further-processed digital signals 463 to a digital display (e.g., VGA display) for viewing or other use. Either or both of the video display unit 160 and the digital signal storage/processing means 170 constitutes an image integration means wherein the individual image lines output by the interpolator 459 and/or C-CLUT modules 451, 452, 484 are integrated into a unified image data structure for viewing, or storage, or further processing.

Those skilled in the art will recognize that it is often advisable to establish the configuration of the image-enhancing and display subsystem 150 before a stream of video-rate image data comes pouring down the pipeline. More specifically, before a frame of image data begins to pass through the CLUT's (451/452 or 484) and through the interpolator 459, it is advisable to define certain system modes such as for example, whether the incoming image data is rendered in 1/555 mode, 1/554/1 mode, P/555 mode or P/554/1 mode. The subposition extraction unit 155 should be preconfigured to extract one or two subposition bits from the instreaming video data and to supply the extracted subposition weighting bits to the interpolator 459 in each display mode other than P/555. In the P/555 mode, the subposition extraction unit 155 supplies default weights to the interpolator 459.

In the case where one of display modes P/555 or P/554/1 are selected, control decoder 154 of multiplexer 152 should be preconfigured to respond to the P/ palette select bit so as to provide dynamic palette selection (in which one of the soft or hard

- 28 -

CLUT sets, 451/452 or 484, is selected on a pixel-by-pixel basis). On the other hand, in the case where either the 1/555 or the 1/554/1 mode is selected, the control decoder 154 should be preconfigured to default  
5 to the user-programmable CLUTs 451, 452 rather than the hardwired CLUT 484. In the case where slipstream overwrite of background pixels is enabled (EnS/S=1), the control decoder 154 of multiplexer 152 should be  
10 appropriately configured to respond to the output of zero detector 351. Also, depending on whether vertical and/or horizontal interpolation is desired, various registers setting the HIon or VIon modes of interpolator 459 should be preloaded with the appropriate settings.

15 Preconfiguration of various parts of the resolution enhancement system 150 preferably occurs during one or both of the vertical blanking period (V-BLANK) that precedes the display of each field or frame, and during the horizontal blanking period  
20 (H-BLANK) that precedes an active horizontal scan period (H-SCAN). The H-BLANK period is relatively short in comparison to the V-BLANK and H-SCAN periods, and as such, preconfiguration operations within the H-BLANK period should be time-ordered and prioritized  
25 to take as much advantage of the limited time available in that slot as possible.

Each video line(s) control block 215.0, 215.1, etc. has a mandatory four-word preamble 310 which is always fetched and executed by the Video Display List  
30 Engine 115'. The mandatory 4-word preamble 310 is optionally followed by a variable length control list 320. The four mandatory control words within preamble 310 are respectively referenced as first through fourth DMA control words 311-314. The data structure  
35 of each of these 4 mandatory words is given in below

Tables 1-4. The optional follow-up list 320 can contain from one to as many as 50 optional control words where the optional control words are of three types: (1) a color-defining word; (2) a video-translator control word; and (3) a display path reconfiguration word. The data structure of the optional color-defining download word is shown in below Table 5. The data structure of the optional display path reconfiguration download word is shown in below Table 6.

TABLE 1

First DMA control word 311 (32 bits), mandatory.

Bit No.s	Field Name	Function
15 31   27		Reserved, must be set to zero for this version
26	SBC	1=doubles the S-Bus clock rate for faster memory fetch rate
20 25   23	Dmode	These 3 bits tell the hardware how many pixels to expect per line. 0=320, 1=384, 2=512, 3=640, 4=1024, 5=reserved, 6=reserved, 7=reserved.
22	EnS/S	1 = Enables Slip Stream capture during H-blanking period.
21	EnVDMA	1 = Enables operation of video DMA.
20	Sels/S	1 = Selects one of two DMA channels as source of slipstream image data or command data.
25 19	VRes	0 = Vertical resolution of incoming data is 240 lines per screen. 1 = Vertical resolution of incoming data is 480 lines per screen.

	18	NexVLCBr	Indicates whether the "next CLUT list" address is absolute (=0) or relative (=1)
	17	NexPline	Specifies whether the "previous video line" address for each subsequent scan line is to be calculated by adding a predefined modulo or by defining it as the previously used "current video line" address.
	16	CAValid	Indicates the validity of the "current line video address" (0= use normally incremented "current line video address", 1= use new address included in current CLUT list instead)
	15	PAValid	Indicates the validity of the "previous line video address" (0= use normally incremented "previous line video address", 1= use new address included in current CLUT list instead)
5	14   9	ListLen	These 6 bits indicate the length in words left to the rest of this list= VLCB_len-4 (-4 because 4 preamble words are always loaded in the current load)
10	8   0	NoLines	These 9 bits indicate the number of additional H scan lines to wait after this line before processing the next VLCB (range= 0 to 2 to-the-9th -1)

TABLE 2

Second DMA control word 312 (32 bits), mandatory.

Current Frame Buffer Address

5	Bit No.s	Field Name	Function
	31   00	cFBA	Physical address from which to fetch first "current" line of pixel data after processing this CLUT list. (Provided CAValid =1.)

TABLE 3

10 Third DMA control word 313 (32 bits), mandatory.

Previous Frame Buffer Address

15	Bit No.s	Field Name	Function
	31   00	pFBA	Physical address from which to fetch first "previous" line of pixel data after processing this CLUT list. (Provided PAValid =1.)

TABLE 4

Fourth DMA control word 314 (32 bits), mandatory.

Next CLUT List Address

20	Bit No.s	Field Name	Function
	31   00	NexVLCB	Address from which the next CLUT list should be fetched, after the number of scan lines specified in the first CLUT DMA control word 311 have been transmitted. The next CLUT list address can be either absolute or relative.

TABLE 5

DMA color-defining word 315 (32 bits), optional.

If Bit 31=0,

Then this is Download Data for Current RGB CLUT's

5	Bit No.s	Field Name	Function
	31	Ctl/Colr (0=Colr)	This first read bit indicates whether the remainder of this 32 bit word is a color palette download word or a display control (command) word. Bit 31 is 0 for a color palette download word. The subsequent bit descriptions (Bits 30-0) in this Table are only valid for the case where Bit 31=0.
10	30   29	RGBen	These 2 bits are write enable bits. 00 = enable a write of the download data of this word to all three current CLUTs (RGB) at the same time. 01 = write the blue field to the blue CLUT only. 10 = write the green field to the green CLUT only. 11 = write the red field to the red CLUT only.
	28   24	Addr	This five bit address field is applied to the RGB CLUT's simultaneously.
15	23   16	RedV	This is the 8 bit Red value to be downloaded if enabled and later output from the Red CLUT when the present address is input.
	15   8	GreenV	This is the 8 bit Green value to be downloaded if enabled and later output from the Green CLUT when the present address is input.
20	7   0	BlueV	This is the 8 bit Blue value to be downloaded if enabled and later output from the Blue CLUT when the present address is input.

If bits 31 and 30 of an optional download word are both one, and if bit 29 is zero (110), then the word is a display control word and contains the following information:

5 Table 6

DMA display-path reconfigure word 316 (32 bits), optional.

If Bits 31,30,29 = 1,1,0.

Then this is Download Command for Display Path

10

Bit No.s	Field Name	Function
31   29	Ctl/Colr  (110=Ctl)	These first-read 3 bits indicate that the remainder of this 32 bit word is a display control (command) word. Bit 31 is 0 for a color palette download word. The subsequent bit descriptions (Bits 28-0) in this Table are only valid for the case where Bits 31:29=110.
15 28	Null	1= forces the audio/video processor to send a null control word to audio/video output circuitry
27	PAL/NTSC	Selects the NTSC or PAL transmission standard for the output. 1=PAL 0=NTSC
26		Reserved
25	ClutBypss	Enables CLUT bypass 484
24	SrcSel	Select source of background overlay data, 1=SlipStream 0=CVBS
20 23	TranTrue	Forces transparency always true mode, letting overlay data be displayed from a slipstream capture if a pixel is defined as being "transparent"
22	EnZDet	Enables the background color detector in the display path to indicate transparency

	21	SwapHV	Swaps the meaning of the horizontal and vertical subposition bits for window color
	20   19	VSrc	Select the vertical subposition bit source as being: a constant 0, a constant 1, equal to a value specified by the corresponding frame buffer bit, or equal to the value of the prior V source setting for window
5	18   17	HSrc	Select the horizontal subposition bit source as being: a constant 0, a constant 1, equal to a value specified by the corresponding frame buffer bit, or equal to the value of the prior H source setting for window
10	16   15	BlueLSB	Select the blue pen LSB source as being: 0, use frame buffer data bit 0, use frame buffer data bit 5, and maintain prior setting for window
	14	VIon	Enables vertical interpolation for window
	13	HIon	Enables horizontal interpolation for window
	12	Rndm	Enables random number generator for the three LSBs of CLUT bypass module 484
	11	MSBrep	Enables a window MSB replication gate
15	10	SwapPENms	Swaps the MSB and LSB of the PEN halfword for line
	9   8	VSrc	Select the vertical subposition bit source as being: a constant 0, a constant 1, equal to a value specified by the corresponding frame buffer bit, or equal to the value of the prior V source setting for line

	<p>7   6</p>	<p>HSrc</p> <p>Select the horizontal subposition bit source as being: a constant 0, a constant 1, equal to a value specified by the corresponding frame buffer bit, or equal to the value of the prior H source setting for line</p>
<p>5   4</p>	<p>BlueLSB</p>	<p>In the case of a x/554/x mode, this field selects the blue pen LSB source as being: 0, use frame buffer data bit 0, use frame buffer data bit 5, and maintain prior setting for line</p>
	<p>3</p>	<p>VIon</p> <p>Enables vertical interpolation for line</p>
	<p>2</p>	<p>HIon</p> <p>Enables horizontal interpolation for line</p>
	<p>1</p>	<p>ColrsOnly</p> <p>Colors Only after this point. Ignore optional download words that are other than color-defining words</p>
<p>10</p>	<p>0</p>	<p>VIoff1ln</p> <p>Disable vertical interpolation for this line only</p>

If bit 31 of an optional color/control word is one, and if bit 30 is zero (10x), then the word contains control information for an audio/video output circuit 105 (not detailed herein) of the system. The audio/video processor circuitry receives this word over the S-bus 123, and forwards it to the audio/video output circuitry for processing. In one embodiment, such translator control words have to be spaced apart from one another by at least four color defining words due to the timing requirements of the configurable video display driver 105.

If bits 31, 30 and 29 of a color/control word are all one (111), then the word contains three 8-bit color fields (red, green and blue) for writing to the "background" pen of the current CLUT module 451.

- 36 -

A DMA stack within the memory-address driver/DMA controller (MAD/DMA) 115 contains an 8-register group (only seven of which are used) to control read transfers out the S-port of VRAM 120'. The S-port transfers themselves do not require control of the D-bus or the address generator, but S-port activity can be controlled only via commands issued over the D-bus. The registers in the group are set forth in Table II.

10

TABLE II

	0	Current CLUT Address
	1	Next CLUT Address
	2	CLUT Mid-Line Address
	3	---
15	4	Previous Line Video Address
	5	Current Line Video Address
	6	Previous Line Mid-Line Address
	7	Current Line Mid-Line Address

In order to coordinate control of the video display path with the display scanning operation, the system of Fig. 1 transmits all of such commands down the display path during an allocated portion of each horizontal blanking period. In particular, about 50 words of transfer time are allotted during each horizontal blanking period. These commands are mostly directed to the color look-up table (CLUT), thereby permitting the CLUTs (there are three CLUTs for a scan line -- one for each primary color) to be updated each scan line. The use of the commands ("color words") by the CLUTs, and the structure of the CLUT system, are described in the related METHOD AND APPARATUS FOR UPDATING A CLUT DURING HORIZONTAL BLANKING application. Other commands ("control words") are directed to the interpolation mechanism, described in the related RESOLUTION ENHANCEMENT FOR VIDEO DISPLAY USING MULTI-LINE INTERPOLATION application. Still

- 37 -

other control words are directed to the audio/video output circuitry 105 and are passed by the audio/video processor to audio/video output circuitry over an AD bus. Note that in another embodiment, other otherwise  
5 unused time slots on the S-bus may be used to transmit commands down the video display path, such as during start-up and/or during vertical blanking.

The control words to be transmitted down the video display path during the allocated portion of the  
10 horizontal blanking period are prepared in advance by the CPU in the form of a linked list (VDL) set up by the CPU in VRAM. Although the control words are not always intended for the CLUTs, this list is sometimes referred to herein as a CLUT list.

15 During frame initialization, (in the vertical blanking period) the CPU 110 can write the address of a new "top of field" CLUT list into register 1 (next CLUT address) of the S-port read transfer group in the DMA stack. If enabled, the top of field CLUT list is  
20 executed at the top of every field by the CLUT control circuitry near the end of scan line 5 (or 4, depending on which field, odd or even, is being generated). To initiate the action, S-port control circuitry of the address manipulator chip issues a request to a DMA  
25 arbiter. When granted, the arbiter transmits the DMA group address for S-port read transfers to a stack address logic unit. The address manipulator chip responsively transfers the corresponding data to the S-port control circuitry. Additionally, the CLUT list  
30 length indication from the control word is loaded into a word counter (not shown), and the number of scan lines to wait before processing the next CLUT list is loaded into a scan line counter (not shown).

After the four mandatory word transfers take  
35 place (311-314), if the CLUT DMA control word

- 38 -

indicates a non-zero number of color/display path control words to follow, the address generator initiates a CLUT list display path transfer. If the number of scan lines to wait before loading the next  
5 CLUT list is zero, then S-port control no longer checks for new transfer requests until the next "top of field" occurs. The top of field CLUT list transfer will take place beginning with the address specified in register 1.

10 If the number of scan lines defined by the NoLines field of the first DMA control word 311 of the first VLCB 215.0 covers the entire screen (e.g., 240 low-resolution lines), then the mandatory and/or optional control words in the next VLCB 215.1 will not  
15 be downloaded or executed because the DMA engine restarts with the first VLCB 215.0 of the then active VDL 215 at the top of each frame.

On the other hand, if the number of scan lines defined by the NoLines field of the first DMA control  
20 word 311 of the first VLCB 215.0 is less than the number needed to cover the entire screen (e.g., less than 240 low-resolution lines), then the mandatory and/or optional control words in the next VLCB 215.1 will be downloaded and executed during the H-BLANK  
25 period preceding the next horizontal scan line that follows the group of scan lines controlled by the first VLCB 215.0.

The last VLCB 215.n in the VDL chain can designate itself or one of the other VLCB's in the VDL  
30 chain as the next VLCB (NexVLCB) and thereby define an endless loop. The hardware automatically restarts at the top of each frame with the first VLCB 215.0 so there is no danger of being trapped in an endless loop.

- 39 -

The basic method for creating a downloadable list of display control words that are to be downloaded from system memory (120) to a configurable image-enhancing and display subsystem (150) has the following steps: (a) define in a first region (215.0) of the system memory (120), a first control word (311) having a ListLen field, where the first control word (311) is to be processed before a corresponding first image line (125.0) is displayed and where the ListLen field indicates a number of additional control words (312-315) that are to optionally follow the first control word (311) before the display of the corresponding first image line; (b) defining in the first memory region (215.0), a second control word (312) following the first control word (311), where the second control word (312) includes a pointer to a memory buffer (125.0) containing at least the to-be displayed first image line; (c) defining in the first memory region (215.0), a third control word (313) following the second control word (312); and (d) defining in the first memory region (215.0), a fourth control word (314) following the third control word (313), where the fourth control word (314) includes a pointer to a next memory region (215.1) having control words to be optionally executed prior to display of another image line, the display of the other image line following the display of said first image line (125.0).

Many variations on this basic process are possible as will now be explained.

Although it is fairly easy for the CPU 110 or another data source to establish a VDL 215 within the VRAM 120' and it is also fairly straightforward to have the CPU 110 designate the VDL as the "currently active" or "master" VDL, such a procedure is fraught

- 40 -

with dangers. It is advisable to use pre-proofed or standardized VDLs which meet certain criteria rather than generating VDLs on an ad hoc basis.

One danger, that has already been mentioned, is that an application program might contain a bug that generates a VDL containing unintended command words for reconfiguring the video display path and/or reconfiguring the digital-to-video translating unit 105 in a manner not intended. Such reconfigurations might disadvantageously "crash" the display subsystem 150 and require a power-up restart in order to fix the problem.

In accordance with a first aspect of the invention, a VDL authenticator or proof-reader 501 is provided within a graphics management folio 500 that is downloaded into system memory 120. The VDL authenticator 501 proofs any custom VDL submitted to it by an application program 600. The authenticator 501 weeds out logically inconsistent portion of the submitted VDL's, depending on context, and produces a proofed copy for use by the system.

By way of example, if an application program 600 submits a custom VDL for approval after system initialization has occurred and the submitted VDL includes commands for reconfiguring the digital-to-video translator 105, the proofer 501 rejects such a custom VDL because it is logically inconsistent with the time of submission.

Proofing speed is enhanced by including a special "Colors-Only" bit (bit 1 of reconfigure word 316 in above Table 6) in the hardware. If the Colors-Only bit is set, the hardware disables any further response during the frame to optional download words other than color-defining words such as word 315 (Table 5). The custom VDL proofer 501 first checks this Colors-Only

- 41 -

bit to see if it is set. If the Colors-Only bit is set, the proofer 501 can avoid wasting time checking remaining words within the VDL since the remaining words will not affect anything other than the CLUT colors. A change of CLUTs colors will not crash the system.

Another feature of the custom VDL proofer 501 is that it places proofed copies of submitted VDL's into VRAM 120' such that each VLCB does not span over an address page crossing. Since the master VDL 215 is to be accessed at high speed by the DMA portion of module 115, it is desirable to position the master VDL 215 within the VRAM portion 120' of system memory and to arrange the VDL such that no Video Line(s) Control Block (VLCB) within the master VDL 215 crosses a memory page boundary. Accordingly, when a custom VDL is submitted for approval to the proofer 501, and the proofer 501 finds the custom VDL to be proper, the proofer 501 reproduces a copy of the VDL in VRAM 120' appropriately positioned to avoid page boundary crossings by the VLCB's.

When the below code of a below-listed Source-code Section is used, a custom VDL is submitted to the graphics management folio 500 for proofing by the statement:

```
int32 SubmitVDL( VDLentry *vdlDataPtr )
```

where vdlDataPtr is a pointer to the custom VDL being submitted by the calling application program to the graphics management folio 500. The custom VDL proofer 501 scans the submitted structure, proofs it for bad arguments, and --if it finds none-- copies the submitted VDL under a logical fence into system RAM. (The prefix "int32" incidentally defines the return code as a 32 bit integer.) The proofed VDL copy can

- 42 -

then be an active VDL by invoking a further call having the structure:

```
int32 DisplayScreen( Item ScreenItemX )
```

5 where X is an "item number" assigned to the proofed VDL. When the SubmitVDL() completes successfully, it returns a "screen item-number" to the calling program. The calling program activates the VDL by submitting the screen item-number to the DisplayScreen() portion of the graphics management folio 500.

10 In the particular implementation of the SubmitVDL() call listed in the below Source-Code Section checks each VDL entry to make sure reserved fields are filled only with zero bits. It also enforces certain hardware restrictions for the  
15 corresponding circuitry. Selection of PAL line width is disallowed because the corresponding hardware supports only NTSC format. Also 640 mode is disallowed, slipstream override is disallowed, and control word transmission to the digital-to-video  
20 translator 105 is disallowed. Moreover, the Colors-Only bit is not taken advantage of in this version. The list of allowed and disallowed modes can of course be modified as desired to conform with different hardware embodiments.

25 Yet another feature of the graphics management folio 500 is the inclusion of a "primary" VDL generator 502 within the folio 500. A set of pre-proofed standard-use VDL structures can be generated by generator 502, thereby avoiding time consumption by  
30 the custom proofer 501. The suite of generated "primary" VDL data structures includes a "simple" type, a "full" type, a "colors-only" type and an "addresses-only" type as will be explained below.

35 Figure 2 shows a first data structure 250 that can be generated by the primary VDL generator 502.

- 43 -

This first data structure 250 is referred to as a "simple", Displayable, Animateable, Image Buffer structure 250 or a "simple DAIB structure 250" for short.

5           The simple DAIB structure 250 has sufficient memory space allocated to it for supporting the following constituent components: (a) a "simple" VDL 251 that consists of a single VLCB 252; (b) a "full" screen buffer 255; and (c) a Cel Animation Destination  
10 Map (CADM) 256. The function of the CADM 256 will be described shortly.

          The full screen buffer 255 contains at least 240 low-resolution lines, where each line has 320 pixels, and each pixel is 16 bits deep. (Depending on the  
15 active display mode, e.g. 1/554/1 or P/555, each pixel can have 14 or 15 bits of color-defining data and 1 or 2 additional bits of other data.) The interpolator 459 of Fig. 1B can be used to increase the apparent resolution of this 320-by-240 full-screen image buffer  
20 255 to 640 pixels by 480 pixels.

          The NoLines field (bits 8:0) in the first DMA control word 311 of the single VLCB 252 is set to a value of 239 image lines or more so that it will span a full screen's-worth (240 lines) of the full-screen  
25 image buffer 255. The second and third DMA control words, 312 and 313, of the single VLCB 252 are set to point to the memory bank addresses containing the top two lines of full-screen image buffer 255. For simplicity sake, these entries are conceptually shown  
30 as a single address pointer 253 pointing to the start of a low resolution image buffer 255.

          The Cel Animation Destination Map (CADM) 256 is a data structure that is used by a set of Draw routines (e.g., DrawTo() ) within the graphics  
35 management folio 500 to control a rendering function

- 44 -

performed by the spryte-rendering engines 109a,b. The CADM data structure is referred to in the below Source-code listing Section as a "BitMap". Each of plural BitMaps is assigned an item number and is addressed by use of that bitmap item number. To fill a rectangular area one would use a call of the following form:

```
int32 FillRect( Item bitmapItem, GrafCon
               *grafcon, Rect *boundary)
```

where bitmapItem is the number of the BitMap (or CADM), Rect \*boundary defines the boundary of the rectangular area, and GrafCon \*grafcon defines the color mix to be used.

Each BitMap, including the illustrated CADM 256 contains an animation-destination pointer 257 pointing to the start or another region of image buffer 255 where new imagery is to be rendered. The CADM 256 further includes a width (W) definition 258 indicating the width of a region within buffer 255 that is to be animated and also a height (H) indicator 259 defining the height of a region within buffer 255 that is to be animated. The cel engines 109a,b render sprytes into buffer 255 in accordance with the information contained in the corresponding cel animation control block (CADM) 256.

At the time of a rendition, the Cel Animation Destination Map (CADM) 256 is logically linked by the Draw routines to a so-called "Spryte-rendition Control Block" or SCoB 104 for short. The SCoB defines the source of new imagery while the CADM 256 defines the destination. A detailed description of the parts of a SCoB 104 and its various functions may be found in the above cited, co-pending applications: U.S. Patent Application Serial No. 07/970,083 (PCT Patent Application Serial No. PCT/US92/09467), entitled

- 45 -

IMPROVED METHOD AND APPARATUS FOR PROCESSING IMAGE DATA, and U.S. Patent Application Serial No. 07/970,289 (PCT Patent Application Serial No. PCT/US92/09462), entitled SPRYTE RENDERING SYSTEM WITH

5 IMPROVED CORNER CALCULATING ENGINE AND IMPROVED POLYGON-PAINT ENGINE. In brief, a SCoB includes a "Next-Pointer" (NEXPTR) which allows it to form part of a linked list of SCoB's. It also includes a "Source-Pointer" (SOURCEPTR) which defines an area in

10 system memory from which a source spryte is to be fetched. It further includes X and Y coordinate values (XPOS, YPOS) which may be converted into an absolute destination address if desired. Various clipping constructs are included both in the

15 definition of a "spryte" and by various hardware registers (simple clip and super-clip) for limiting the area into which the spryte-rendering engines (cel animation engines) 109a,b write.

The image buffer 255, the display pointer 253

20 pointing thereto, and the animation-destination pointer 257 also pointing thereto, are preferably all defined within memory unit 120 at the same time so that independent display operations and spryte rendering operations can be performed on respective

25 parts of the same image buffer 255 that are pointed to by the display pointer 253 and the animation-destination pointer 257.

When the simple VDL 251 of Fig. 2 is designated by the CPU 110 as being the master VDL, then the Video

30 Display List Engine portion 115' of the DMA engine 115 will cause the contents of image buffer 255 to be displayed on the screen of monitor 160 (and/or sent to the digital signal storage/processing means 170) in accordance with the information contained in the

35 single VLCB 252.

- 46 -

It is to be understood that the image data within buffer 255 is not necessarily the image data that is being displayed on monitor 160 (or sent to the digital signal storage/processing means 170) at a given time. It becomes the displayed image when the simple VDL 251 is made the master VDL. The logical connections (253, 254) that are made between the simple VDL 251 and the full-screen image buffer 255 make it possible to quickly display the contents of buffer 255 simply by naming VDL 251 as the master VDL. Until VDL 251 is named master, the image information pointed to by fields 253 and 254 of VDL 251 are in a stand-by state, ready to be displayed rather than being actually displayed. Hence the term "displayable" rather than "displayed" is used in defining this simple DAIB structure 250. (It should be understood that a VDL other than 251 can point to part or all of buffer 255 at the same time, and if that other VDL is active, the pointed to parts of buffer 255 may be displayed by way of that other VDL even though VDL 251 is not active at the time.)

It is to be additionally understood that the cel engines (spryte-rendering engines) 109a,b are not necessarily writing sprytes into a region or all of image buffer 255 at any given time. The Cel Animation Destination Map (CADM) 256 constitutes a data structure that stands ready for directing the cel engines 109a,b to render sprytes into buffer 255 when desired. Hence the term "animateable" rather than "animated" is used in describing the DAIB structure 250. The cel engines 109a,b can be writing to buffer 255 regardless of whether all or parts of it are being currently displayed or not. The Video Display List Engine 115' can be displaying the contents of buffer 255, or not, regardless of whether the cel engines are

- 47 -

or are not concurrently writing new image data into buffer 255. The display and render functions can be actuated independently of one another so that they occur either both at a same time or at different times, one after the next.

Figure 3 shows the data structure of a more complex, "split, double-buffered" DAIB structure 260. The split, double-buffered DAIB structure 260 includes a first VDL 261 and a second VDL 271. The first VDL 261 has two VLCB's, 262 and 264, defined therein. The threaded-list link 269 that joins VLCB 262 to VLCB 264 is preferably based on relative addresses rather than absolute addresses. The image source pointer 263 of first VLCB 262 points to a first image buffer 265. The image source pointer 283 of second VLCB 264 points to a second image buffer 285.

The NoLines field of VLCB 262 is set so that the number of image lines to be displayed out of the first buffer 265 is less than that used for filling an entire screen (e.g. less than 240 low resolution lines). The NoLines field of VLCB 264 is similarly set so that the number of image lines to be displayed out of the second buffer 285 is similarly less than that needed for filling an entire screen. When buffers 265 and 285 are stitched together, however, by VDL 261, --and VDL 261 is made active-- the image lines of buffers 265 and 285 combine to fill all or a significant portion of the screen 165. (VLCB 262 is downloaded into the hardware during a first H-BLANK period and VLCB 264 is downloaded into the hardware during a second H-BLANK period further down the same frame.)

For purposes of example, it will be assumed that the displayable imagery of buffer 265 fills a top portion of the display screen and the displayable

- 48 -

imagery of buffer 285 fills a remaining bottom portion of the display screen. More specifically, it will be assumed that the lower buffer 285 contains the imagery of a control panel such as used in an airplane cockpit or on an automobile dashboard.

It will be further assumed that a real-time game or simulation program is being executed on the image processing and display system 100, and the image 165 on video display unit 160 is showing the pilot's or driver's view of what is happening during a fast-paced flight simulation or a car-racing simulation, both inside and outside the vehicle. It will be assumed that the upper portion of the screen (buffer 265 of Fig. 3) contains the "outside world" view -- in other words, what would be seen through the windshield of the simulated vehicle as the vehicle (e.g., airplane or car) moves and changes directions.

During a fast-paced game or simulation, many changes will have to be made to what is shown through the windshield of the simulated airplane/car. The background scenery changes quickly as the vehicle changes orientation. Other moving objects (e.g., other airplanes or cars) quickly move in and out of the scenery displayed through the windshield.

In light of this, there is a need to make fast-paced, bulk modifications to the imagery contained in the upper-screen buffer 265. Buffer 265 is accordingly referred to here as a first bulk/fast modification buffer. The term "bulk/fast modification" is intended to imply that fast-paced changes and/or changes to a bulk portion of the imagery in the buffer have to be often made on a real time basis as the game/simulation proceeds.

A first Cel Animation Control Buffer (CADM) 266 is shown logically coupled to the first bulk/fast

- 49 -

modification buffer 265 for enabling the spryte engines 109a,b to write image modifications into buffer 265.

In contrast to the rapid and/or major changes that need to be made to the outside-world view that comes through the windshield, no or very few modifications have to be made to the control panel of buffer 285 over relatively long spans of time. Perhaps an instrumentation needle may have to be moved a slight amount one way or another; or an indicator light may have to be switched on or off, but the rest of the control panel remains basically unchanged. Also, the player is probably focusing most of his/her attention on the fast-paced imagery coming through the top window and probably paying much less attention to what is being displayed on the control panel. So when changes are to be made to the imagery of the bottom buffer 285 they tend to be of a minute nature and often times they are not time critical --meaning that they can be often put off for a later time, when a time slot conveniently opens up in the play action for downloading the control panel changes.

In light of this, buffer 285 is referred to as the slow/small/no modification buffer 285. A second Cel Animation Destination Map (CADM) 286 is shown logically coupled to the small/no modification buffer 285 for allowing the spryte engines 109a,b to write into buffer 285.

The second VDL 271 is structured similarly to the first VDL 261 and has corresponding third and fourth VLCB's 272 and 274 linked by relative thread 279. The fourth VLCB 274 points to the small/no modification buffer 285 in substantially the same way that the second VLCB 264 points to that same small/no modification buffer 285. The third VLCB 272, on the

- 50 -

other hand, points to a third buffer 275 which is referred to here as the second bulk/fast modification buffer 275. A third Cel Animation Destination Map (CADM) 276 is logically coupled to the second  
5 bulk/fast modification buffer 275 for allowing the cel animation engines 109a,b to write new imagery into buffer 275.

The problem of image tear has been discussed above and will not be repeated here. One solution to  
10 the tear problem is to double buffer the entire screen, but this wastes memory space, particularly when one or more bands of the screen (such as the above-described cockpit control panel) will have no or only a few minute changes made to their contents over  
15 relatively long periods of time.

The better approach is to use the split, double-buffered DAIB structure 260 of Fig. 3. The application program periodically swaps the designation of the currently active VDL back and forth between the  
20 first VDL 261 and the second VDL 271. When the first VDL 261 is the active video display list, the screen shows the first bulk/fast modification buffer 265 filling its top and the small/no modification buffer 285 filling the bottom of the screen 165. The first  
25 CADM 266 is taken off the activity queue of the spryte engines 109a,b so that the spryte engines 109a,b will not write to the first bulk/fast modification buffer 265 during the time that buffer 265 is being actively displayed.

30 The second CADM 286 is kept on the activity queue of the spryte engines 109a,b during this time. Because no changes or only a few minute changes will be made on-the-fly to buffer 285, it is unlikely that a noticeable tear will occur in the imagery of buffer  
35 285, even if the spryte engines 109a,b are writing to

- 51 -

a line of buffer 286 at the same time that the display beam of video display unit 160 is moving through that same line. This might be seen as a small twitch in the length of an advancing instrumentation needle and will probably not draw attention.

At the same time that the image buffers of VDL 261 are being actively displayed, the third cel animation control block (CADM) 276 is placed on the activity queue of the spryte engines 109a,b so that the spryte engines 109a,b can make major changes to the imagery contained in the second bulk/fast modification buffer 275. The rendition operation of the spryte-rendering engines 109a,b is started. Because buffer 275 is not being actively displayed at this time, there is no danger that a noticeable tear will appear on the display screen due to major modifications then being made to the imagery of buffer 275 by the spryte-rendering engines 109a,b. Minor changes to buffer 285 are unlikely to draw notice even if they cause a slight glitch in the then displayed imagery.

When desired changes to the second bulk/fast modification buffer 275 and to the small/no modification buffer 285 have completed, the spryte-rendering engines 109a,b signal the CPU 110 that they have completed the job. The CPU 110 then designates the second VDL 271 as the active video display list while making the first VDL 261 nonactive. The third CADM 276 is taken off the activity queue of the spryte engines 109a,b and the first CADM 266 is placed onto the activity queue of the spryte engines 109a,b. The spryte-rendering engines 109a,b are restarted. The screen of monitor 160 will now show the contents of the second bulk/fast modification buffer 275 at its top and the contents of the small/no modification

- 52 -

buffer 285 still filling the bottom of the screen. This new combination is indicated by the dash dot lines linking buffers 275 and 285.

Major changes to the first bulk/fast modification  
5 buffer 265 are made in the background by the restarted  
spryte-rendering engines 109a,b while the combination  
of buffers 275 and 285 are displayed in the  
foreground. When the new spryte rendering operation  
completes, the first VDL 261 is again made the active  
10 video display list while the second VDL 271 is made  
inactive. The swapping process repeats with the  
completion of each rendition by the spryte-rendering  
engines 109a,b. The split buffer nature of this  
approach has the benefit of reducing the amount of  
15 memory and time consumed by double buffering.

While the above description of Fig. 3 used the  
example of a screen that is split into two parts (a  
top windshield and a bottom control panel), it should  
be apparent that much more complex structures can be  
20 formed by appropriate linking of VLCB's to form  
different varieties of VLD's. By way of example, a  
same horizontal band of a given image buffer (e.g.,  
265) can be repeatedly called into different parts of  
a displayed screen by a series of VLCB's in a long-  
25 chained, active VDL. A one time change to the  
contents of the repeatedly-called buffer band will be  
multiplied on the screen by the number of times that  
same band is called by the active VDL.

For purposes of speaking, it is useful to define  
30 the set of horizontal image bands that are stitched  
together by a VDL as a "virtual screen". Each virtual  
screen has a single Video Display List (VDL)  
associated with it. Thus, in Fig. 3, image bands  
from buffers 265 and 285 become stitched together to  
35 define a first "virtual screen". The first VDL 261 is

- 53 -

the VDL associated with that first virtual screen. Image bands from buffers 275 and 285 become stitched together to define a second "virtual screen". The second VDL 271 is the VDL associated with that second  
5 virtual screen. Double-buffering is performed by periodically switching the "active" virtual screen designation back and forth between the first virtual screen (265 plus 285) and the second virtual screen (275 plus 285).

10 A triple-buffering process can be set up by establishing an array of three virtual screens (not shown) and rotating the active designation among them. More generally, an n-buffering process can be set up by establishing an array of n virtual screens and  
15 rotating the active designation among them. The array of n virtual screens is referred to a "screen group".

A generalized approach to creating a screen group and displaying the imagery extracted from that group can be explained by the following procedure guide:

20 PROCEDURE GUIDE FOR CREATING AND DISPLAYING SCREENS  
**CREATING A SCREEN GROUP**

Displaying a "virtual screen" within an executing task is a three-level process: You first create a "screen group" composed of an array of one or more  
25 virtual screens, you then add the screen group to a displayable set in the graphic folio's display mechanism, and finally you display a screen from the group by making it the active or master screen.

Creating a "screen group" can be a fairly  
30 involved step --or it can be extremely simple, depending on whether you chose to create your own custom set of screens or you use a provided set of default screen group settings. This section describes

- 54 -

your options in defining a screen group and its components.

#### **The CreateScreenGroup() Call**

To create a screen group, use the procedure call:

```
5      Item CreateScreenGroup( item *screenItemArray,  
                             TagArg *tagArgs )
```

The first argument is a pointer to a one-dimensional array with one element for each screen in the screen group. You must dimension the array so that it contains at least as many elements as the screen group has screens. When CreateScreenGroup() is executed, it creates the number of screens specified in its tag arguments, and fills in the array elements with an item number for each screen. You use the item numbers to refer to any screen in the group.

The second argument is a pointer to a list of tag arguments (tag args), groups of values that specify the attributes of the screen group. Each tag arg is a pair of 32-bit values. The first value (ta\_Tag) specifies which attribute of the screen group is being defined; the second value (ta\_Arg) specifies how that attribute is defined. The list can contain a variable number of tag args in any order; it must be terminated, however, with a CSG\_TAG\_DONE tag arg so the call knows when it's finished reading tag args.

CreateScreenGroup() assumes that any tag arg not sullied in the tag arg list is set to a default value. For example, if the tag arg for the screen count is not in the list, CreateScreenGroup() sets the screen count to the default value of 1. If you want CreateScreenGroup() to create a screen group with nothing but default values, you can substitute "NULL" for the tag arg list pointer. You then create a screen group with a single 320x240 screen, a single 320x240 bitmap, and a standard (simple) VDL.

- 55 -

When CreateScreenGroup() executes, it creates and links together the data structures that define the bitmaps, VDLs, screens, and other components of the screen group. It also allocates any resources  
5 necessary to create the screen group (such as VRAM for bitmap buffers). When finished, it returns zero to indicate success, or a negative number (an error code) if it was unsuccessful.

The sections that follow describe the tag args  
10 you can use with the CreateScreenGroup() call.

#### **Setting the Screen Count and Dimensions**

The tag arg CSG\_TAG\_SCREENCOUNT sets the number of screens in the screen group. Its value is the integer number of screens you want in the group; you  
15 should set it to the appropriate number for your purposes: two for double-buffering, three or four for double-buffered stereoscopic display, etc. (Stereoscopic display relies on the use of LCD shutter glasses that alternately show interlaced fields to  
20 an observer's left and right eyes.) The default value for this tag arg is one.

Be sure that the returned screen item number array you create for the CreateScreenGroup() call has at least enough elements to contain the number of  
25 screens you specify here.

The tag arg CSG\_TAG\_SCREENHEIGHT sets the height in pixels of the buffer for each screen in the screen group. (The buffer is the combined VRAM of all of each screen's bitmaps.) The default value is 240,  
30 which is the maximum number of visible rows in the NTSC display, but you can set the height to be larger (so you can hide parts of the screen off the display) or smaller (so you can reveal other screen groups below this one).

- 56 -

The tag arg `CSG_TAG_DISPLAYHEIGHT` sets the height in pixels of the visible portion of each screen in the screen group. The display height can't be set to reveal more of a screen than exists, so this value must always be less than or equal to the screen height value. When you set a value here that's less than the screen height, the bottom rows of the screen group are hidden in the display, an effect that can reveal other screen groups beneath this one. When you set a value that's greater than the screen height, added rows of black appear at the bottom of the screen. The default display height is 240, enough to fully display a default screen height.

Note that both `CSG_TAG_SCREENHEIGHT` and `CSG_TAG_DISPLAYHEIGHT` must be set to an even number. That's because the frame buffer stores pixels in left/right format, binding pairs of odd and even frame buffer together in VRAM. If you specify height with an odd number, the graphics folio rounds the value up to the next higher even number.

#### **Setting Bitmap Counts, Dimensions, and Buffers**

The tag arg `CSG_TAG_BITMAPCOUNT` sets the number of bitmaps within each screen of the screen group. You must have at least one bitmap; you can, in theory, have one bitmap per screen row if you wish. It's easier, however, to manage a more reasonable number of bitmaps--less than ten, for example. If you don't specify a bitmap count, the default is one bitmap per screen.

The tag arg `CSG_TAG_BITMAPWIDTH_ARRAY` controls the width of each bitmap set in the bitmap count. It contains a pointer to a one-dimensional array of 32-bit integer values, one value for each bitmap. The values in the array apply to the bitmaps within a

- 57 -

screen starting with the top bitmap, working down to the bottom bitmap. Each array value sets the width in pixels of its corresponding bitmap. Bitmaps may be wider than their parent screen, in which case the rightmost columns of the bitmap are truncated from the screen, and not displayed. Bitmaps may also be narrower than their parent screen, in which case they appear flush on the left side of the screen.

A bitmap's width may be set to only one of a set of possible widths. Those widths are 32, 64, 96, 128, 160, 256, 320, 384, 512, 576, 640, 1024, 1056, 1088, 1152, 1280, 1536, and 2048. The default bitmap width is 320 pixels, which exactly matches the screen width of the NTSC display.

The tag arg `CSG_TAG_BITMAPHEIGHT_ARRAY` controls the height of each bitmap set in the bitmap count. Like the bitmap width tag arg, this tag arg points to a one-dimensional array of 32-bit integer values, one for each bitmap, going from the top bitmap to the bottom bitmap. You don't need to set this tag arg if there is only one bitmap set per screen (in which case the bitmap height is set to 240), but you must set bitmap heights if there is more than one bitmap per screen.

Bitmaps are contiguous within the screen; one bitmap picks up where the last bitmap left off. If the combined bitmap heights are greater than the screen height, then the bottom rows of the bottom bitmap (or bitmaps) are clipped from the screen. If the combined bitmap heights are less than the screen height, then the bottom of the screen is empty--filled with 000 pixels. <<<In a planned future release of Portfolio, bitmaps may be able to be positioned within a screen using a Y offset.>>>

- 58 -

The tag arg `CSG_TAG_BITMAPBUF_ARRAY` lets you specify a bitmap buffer in VRAM for each bitmap--if you're intent on doing it by hand, and don't let the graphics folio do it for you automatically. If you skip this tag arg altogether, you can live a life of leisure: the graphics folio specifies all the bitmap buffers on its own. If you decide to use this tag arg, its value is a pointer to one-dimensional array of pointers, one per bitmap. The bitmap order is top to bottom in the first screen, top to bottom in the next screen, and so on. Each bitmap pointer points to the starting address in VRAM of the bitmap buffer.

Note that the bitmap buffer array must contain one entry for each bitmap in the screen group. For example, if a screen group has two screens and each screen has three bitmaps, then the array must contain six pointers, one for each bitmap. Those pointers can, of course, point to the same address if you want to share a buffer among bitmaps.

The tag arg `CSG_TAG_SPORTBITS` is the last bitmap tag arg. It controls the location of the bitmap buffers when they're allocated so that the buffers are capable (or not, if so specified) of using SPORT transfers. SPORT transfers are used for refreshing bitmap backgrounds between frames, erasing cel projections and other per-frame renderings to start with a fresh background for new projections and renderings. (SPORT transfers are S-bus data downloads occurring during the V-BLANK period.)

SPORT transfers between bitmap buffers (or within a bitmap buffer) require that the buffers reside within the same bank of memory, so it's important that the buffers be placed together within the same bank when allocated. Banks of VRAM are specified with a 32-bit mask whose bits show selected VRAM banks. The

- 59 -

kernel call `GetBankBits()` accepts a pointer to any memory location, and then returns a bank mask with the proper bits set to show within which VRAM bank the memory location resides.

5       If you provide a 32-bit bank mask specifying a single VRAM bank for `CSG_TAG_SPORTBITS`, bitmap buffers are allocated within that specified bank. If you provide a null mask (all bits set to 0 so no banks are specified), all bitmap buffers are allocated within a  
10       single unspecified bank of memory so that SPORT transfers are possible among all bitmaps. And if this tag arg is left out altogether, bitmap buffers are placed in any available VRAM without regard to banks, so that SPORT transfers among bitmaps may not be able  
15       to take place.

      Note that `CSG_TAG_SPORTBITS` settings apply to bitmap buffers whether you specify each buffer by hand with the `CSG_TAG_BITMAPBUF_ARRAY` tag arg or if you leave the tag arg out and let the graphics folio  
20       specify bitmap buffers for you.

#### **Setting Screen VDL Types and Attaching Custom VDLs**

      The tag arg `CSG_TAG_VDLTYPE` specifies the type of VDL supplied for each screen of the screen group--one type for all the screens in the group. The VDL type  
25       specified here is used whether you supply your own "custom" VDLs (in which case this tag arg tells `CreateScreenGroup()` what kind of VDLs you're supplying), or the graphics folio supplies VDLs for you (in which case it tells the graphics folio what  
30       kind of VDLs it must create).

      The five types of "noncustom" VDLs you can specify here are:

- `VDLTYPE_SIMPLE`, which has one entry. This entry points to a single bitmap buffer, and  
35       defines a single VLCB having one set of CLUT

- 60 -

and display control words. The single bitmap buffer and VLCB (CLUT, and display control settings) are used for the entire screen.

- 5           •    VDLTYPE\_FULL, which has an entry for each line of the display. Each entry has its own bitmap buffer pointer and its own VLCB (set of CLUT and display control words).
- 10           •    VDLTYPE\_COLOR, which has an entry for each line of the display. Each entry has only a full CLUT, and does not (and can not) include a bitmap buffer pointer or a display control word. The colors of the CLUT are changeable on a line by line basis while the display control remains fixed for the entire screen and the bitmap remains the same for the entire screen. <<<This type of VDL isn't supported yet in the below listed Portfolio.>>>
- 15
- 20           •    VDLTYPE\_ADDRESS, which has an entry for each line of the display. Each entry has only a bitmap buffer pointer, and does not (and can not) include CLUT and display control words. The address from which a screen band will be fetched for display is changeable on a line by line basis and the corresponding bitmap for rendering to each band can be changed on a line by line basis; but the display control and the colors of the CLUT remain fixed for the entire screen. <<<This type of VDL isn't supported yet in the below listed Portfolio.>>>
- 25
- 30
- 35           •    VDLTYPE\_DYNAMIC, which can be modified freely both in terms of address per line and CLUT per line. <<<This type of VDL isn't support yet in the below listed Portfolio.>>>

The default VDL type is VDLTYPE\_SIMPLE.

40           If you're bold and decide to create your own VDLs, the tag arg CSG\_TAG\_VDLPTR\_ARRAY lets you point to a custom VDL for each of the screens in the screen group. It contains a pointer to an array of VDLs, each of which must match the type specified in the previous tag arg. If you don't specify an array of

- 61 -

VDLs here, then the graphics folio will create them for you. The graphics folio provides a set of VDL calls that create VDLs and submit them to the system for approval.

- 5       Note that if you create a custom VDL, the graphics folio ignores all the previous tag args about bitmaps because your custom VDL will have to define its own corresponding bitmap or bitmaps.

#### **CREATING CUSTOM SCREEN VDLs**

- 10       Several procedure calls create, modify, and connect a VDL to a screen. Your first task is to create a VDL data structure to submit to the system. You can create any of the five VDL types described earlier in the VDL tag args section:

#### **15    The Simple VDL Data Structure**

A single VLCB (Video Line/s Control Block) linked to a single image buffer which is then linked to a single bitmap (CADCM, see Fig. 2).

#### **The Full VDL Data Structure**

- 20       240 VLCB's threaded one to the next, each with its own CLUT palette and source address and rendition-controlling bitmap.

#### **The Color VDL Data Structure**

- 25       240 VLCB's threaded one to the next, each with its own CLUT palette. Only the first VLCB defines a source address and rendition-controlling bitmap. The remaining VLCB's refer to the remaining contiguous lines of a single 240 line image buffer.

- 62 -

**The Address VDL Data Structure**

240 VLCB's threaded one to the next, each with its own source address and rendition-controlling bitmap. Only the first VLCB defines the CLUT palette. The remaining VLCB's rely on the CLUT palette downloaded by the first VLCB.

**The Dynamic VDL Data Structure**

<<<This section to be filled in when the VDL data structure is defined.>>>

**10 Submitting a Screen VDL**

Once you've created a custom screen VDL data structure, you submit it to the system with the procedure call:

```
int32 SubmitVDL( VDLEntry *vdlDataPtr )
```

15 The single argument submitted to this call is a pointer to your custom VDL data structure. Portfolio reads the data structure, proofs it for bad arguments, and--if it finds none--copies the VDL under the fence, into system RAM, as a screen VDL. It returns an item number for the screen VDL, which you can use in a CreateScreenGroup() tag arg to associate the VDL with a newly-created screen in a screen group. You can also use the VDL item number to specify the VDL when you modify it or its connections.

**25 Modifying a VDL**

To modify the contents of a screen VDL in system RAM, use the procedure call:

```
long ModifyVDL( item IVDL, long linenumber, long *Targs )
```

30 The first argument specifies the screen VDL, the second argument specifies the number of the VDL line to receive the modification, and the third argument

- 63 -

points to a tag arg array that describes the changes to be made to the VDL.

The call returns a zero to indicate success, or an error code (less than zero) if there was a problem.

5 Note that you can't modify a screen VDL by modifying the VDL data structure you used to first create that VDL. It now exists in system RAM, and must be modified using ModifyVDL().

#### **Setting a New VDL for an Existing Screen**

10 If you've already created a screen in a screen group and want to assign a different screen VDL to that screen, use the procedure call:

```
int32 SetVDL( Item screenItem, Item vdlItem )
```

15 The first argument specifies the screen to which you want to assign a new screen VDL, and the second argument specifies the screen VDL that you want to assign.

#### **Deleting a VDL**

20 To delete a screen VDL, use the call DeleteItem(), and supply it with the item number of the screen VDL to delete. If you delete a VDL that is in use, the screen depending on that VDL goes black.

#### **SETTING A SCREEN'S COLOR PALETTE**

25 The contents of a screen's CLUT set determine the color palette available to the pixels in the screen. If you don't specify any custom colors for a screen, then the screen uses the default CLUT set, the fixed CLUT set. The fixed palette contains a linear ascending color palette.

30 If you want to set a custom color palette for a screen, you can do so by creating a custom VDL, which can be an involved process, as you just read. This

- 64 -

method lets you change color palettes from line to line within a screen. If you simply want to set a color palette for an entire screen that uses a simple VDL (one that doesn't change parameters from line to line), then you can use the much simpler graphics folio color calls. These calls accept new color entries for a screen's CLUT set and then revise the screen's VDL appropriately. You don't have to deal with the VDL directly.

#### 10 **A CLUT Set Review**

As you'll recall from the above discussion, the display generator reads pixels from the frame buffer. Each frame buffer pixel has a 15-bit color value: five bits devoted to red, five to green, and five to blue (in the 1/555 mode). Those values enter the CLUT (Color LookUp Table) set, which has a separate lookup table for red, green, and blue. Each CLUT register stores an eight-bit value.

When a 15-bit RGB value enters the CLUT set, it's broken into its red, green, and blue components. Each component enters the appropriate CLUT, where it selects a corresponding eight-bit red, green, or blue value. The three outputs are combined into a 24-bit RGB value that is then used for that pixel in the rest of the display generator.

The CLUT for each color has 33 registers: numbers 0-31 are for direct color indexing; number 32 is for any pixel marked as background. Although red, green, and blue are separated when they enter the CLUT set, and although the CLUT set is treated as three CLUTs, one for each color, the physical reality of the CLUT hardware is that each CLUT register extends across all three colors. That is, each register is 24 bits wide. The first eight bits are for red, the second eight

- 65 -

bits for green, and the last eight bits for blue. When the VDLP (Video Display List Processor or engine) writes a new register value into the CLUT set, it writes a 24-bit value that changes red, green, and blue for that register number. For example, if the VDLP sets a new value for register 3, it writes a 24-bit value that changes red register 3, green register 3, and blue register 3.

### Specifying a New Color

10 To set a new color in the CLUT set, you must first specify which CLUT register you want to set, and then specify the 8-bit red, green, and blue values you want in that register. Use this call to specify red, green, and blue together and then return a value you can then use to set red, green, and blue within a CLUT register:

```
int32 MakeCLUTColorEntry( index, red, green, blue
)
```

20 The call accepts an unsigned index byte that indicates which CLUT set register you want to change. A value of 0 to 31 indicates registers 0 to 31 in the CLUT set; a value of 32 indicates the background register.

25 The call also accepts an unsigned byte each for the red, green, and blue value you want to set in the CLUT set register. A minimum value of 0 indicates none of the color, while a maximum value of 255 indicates as much of the color as possible.

30 MakeCLUTColorEntry() returns a 32-bit value that you can use with the color-setting calls to change CLUT set registers.

To specify only a red, a green, or a blue value to write into a CLUT register without touching any of

- 66 -

the other color values in the register, use these three calls:

```

int32 MakeCLUTRedEntry( index, red )
int32 MakeCLUTGreenEntry( index, blue )
5   int32 MakeCLUTBlueEntry( index, blue )

```

Each call accepts an unsigned index byte to indicate which CLUT set register you want to change, and then accepts an unsigned byte with that signifies a red, green, or blue color value you want to set.

10 Use MakeCLUTRedEntry() to specify a red value, MakeCLUTGreenEntry() to specify a green value, and MakeCLUTBlueEntry() to specify a blue value.

Each of these calls returns a 32-bit value to use with a color-setting call.

#### 15 **Setting a New Color Register Value in the CLUT Set**

The simplest of these is this call:

```

int32 SetScreenColor( Item screenItem, int32
colorEntry )

```

20 SetScreenColor() accepts the item number of the screen for which you want to change the color palette. It also accepts a color entry value created by any of the four CLUT entry calls: MakeCLUTColorEntry(), MakeCLUTRedEntry(), MakeCLUTGreenEntry(), and MakeCLUTBlueEntry(). The color value specifies the  
25 color register and the colors you want to change. SetScreenColor() then changes the screen's VDL so that the screen uses the custom CLUT set (if it was using the fixed CLUT set) and so that the appropriate register in the CLUT set uses the new color or colors  
30 you specified.

SetScreenColor() returns a zero if successful, or a negative number (an error code) if unsuccessful.

- 67 -

**Setting Multiple New Color Register Values in the CLUT Set**

If you want to set more than one color in a screen's palette at a time, use this call:

```
5      int32 SetScreenColors( Item screenItem, int32
      *entries, int32 count )
```

The call accepts the item number of the screen for which you want to change the palette. It also accepts a pointer to a list of 32-bit color entries and a 32-bit count value that gives the number of entries in the list. Each of the color entries is a value set by one of the four CLUT entry calls.

When SetScreenColors() executes, it reads each color entry, and then changes the specified screen's VDL appropriately so that it uses the custom CLUT set and writes the specified colors into the specified CLUT set registers.

**Reading Current CLUT Set Registers**

You may occasionally need to read the color value currently stored in a CLUT set register. To do so, use this call:

```
RGB888 ReadScreenColor( ulong index )
```

It accepts an index number from 0 to 32 which specifies registers 0 to 31 or the background register (32) of the CLUT set. It returns a 24-bit RGB value if successful. The first byte of the RGB value is red, the second is green, and the third is blue. The call returns a negative number (an error code) if unsuccessful.

**30 Resetting the Fixed Palette for a Screen**

If you want a screen to abandon its custom palette and return to the linear ascending color of the fixed palette, use this call:

- 68 -

```
int32 ResetScreenColors( Item screenItem )
```

It accepts the item number of the screen for which you want to reset the palette and, when executed, changes the screen's simple VDL so that it specifies the fixed CLUT set for the entire screen. It returns a zero if successful, or a negative number (an error code) if unsuccessful.

#### DISPLAYING A SCREEN GROUP

Once a screen group and its components are defined, you use further graphics calls to display the screens of a given screen group in a video frame.

#### Adding a Screen Group to the Display

The first step in causing the screens of a screen group to show up in the displayed video, is to add the data structure for the screen group to the graphics folio's display mechanism, which you do with this call:

```
int32 AddScreenGroup( Item screenGroup, TagArg *targs )
```

The first argument is the item number of the screen group which you wish to add. The second argument is a list of tag args that defines how the screen group is to be placed in the display. <<<These tag args don't exist in the below-listed, latest release.>>>

This call returns a zero if the screen group was added to the display mechanism; it returns non-zero (an error code) if anything went wrong and the screen group was not added.

#### 30 Displaying Screens

Once the data structure of a given screen group has been added to the display mechanism, you can display any of its screens (which includes all of the screens' visible bitmaps) by using the procedure call:

- 69 -

```
int32 DisplayScreen( Item ScreenItem0, Item
ScreenItem1 )
```

This call accepts two arguments, each the item number of a screen within the same screen group. The first screen is displayed in the odd field of a frame; the second screen is displayed in the even field of the same frame.

If you want to display a stereoscopic image from a screen group, specify two different screens in this call: the right screen first, the left screen second. If you don't want a stereoscopic image and instead want the same image displayed in both fields of the frame, you can either specify the same screen for both arguments, or you can pass a null value for the second argument.

DisplayScreen() returns zero if it was successful. It returns a value less than zero (an error code) if it wasn't successful.

#### **Double-Buffering**

To use a two-screen group for double-buffered animation, issue a DisplayScreen() call during each vertical blank. In one frame, specify one screen alone for display, and render to the other screen. In the next frame, specify the second screen alone for display, and render to the first screen. Continue alternating as long as the animation continues.

Double-buffering a stereoscopic display works much the same way, but instead of alternating between single screens in each frame, alternate between pairs of screens.

#### **Multiple Screen Groups**

When a screen appears in a display where screens from other screen groups are also present, the

- 70 -

screen's position attributes (set in the tag args of AddScreenGroup()) determines what screen is on top of what other screen. A screen with a position attribute of "bottom" will appear beneath all other screens present; a screen with a position attribute of "top" will appear above all other screens. If a screen doesn't fill the entire frame, any screens displayed beneath it will show through.

### Moving Visible Screens

10 <<<Note: In the below listed latest release of Portfolio, this call does not yet exist.>>>

Once a screen is displayed, you can change its position in the frame with this call:

15 int32 MoveScreenGroup( Item screenGroup, Coord x,  
Coord y, level )

This call accepts the item number of the screen group that you wish to move, and accepts X and Y coordinates to specify the location within the frame where you want to screen group to move. The coordinates are figured from the frame's origin, which falls in the upper left corner of the frame. MoveScreenGroup() also accepts a level argument, a value that specifies whether the screen group appears on top of, at the bottom of, or in between any other screen groups in the display. <<<The level value is TBD. When it's set, a table will go here with those values.>>>

Note that whatever level you set with this call may not endure. Another screen group can change in relationship to this screen group, or the user might decide to pop another screen above or below this screen.

- 71 -

### Removing a Screen Group From Display

Once a screen is displayed with the DisplayScreen() call, it remains in the frame until the screen's screen group is removed. To remove a screen group, use this procedure call:

```
int32 RemoveScreenGroup( Item screenGroup )
```

This call accepts the item number of the screen group that you wish to remove. It removes the group from the graphics folio's display mechanism, but the group's data structures and resource allocation remain intact. You may redisplay the group at any time with another AddScreenGroup() call followed by a DisplayScreen() call.

RemoveScreenGroup() returns a zero if successful, and returns a negative number (an error code) if it failed.

### Deleting a Screen Group

To completely delete a screen group, including the data structures used for its definition and all of its allocated resources, use the call DeleteItem(), and supply it with the item number of the screen group.

Note that anytime a task quits, any of its screen groups are automatically deleted.

## 25 RENDERING INTO A SCREEN

You can render into a screen by projecting a cel, drawing a graphics primitive, or rendering text. To project a cel, use either the DrawScreenCels() or the DrawCels() call. The first call projects a cel (or cel group) into a full screen even across multiple bitmaps if the screen has them. The second call restricts cel projection to a single bitmap, which is no restriction to single bitmap screens, but can

- 72 -

create interesting effects in multiple. You'll find more details about both cel calls in the next chapter, "Using the Cel Engine."

To draw directly to a screen's bitmaps without the cel engine, use the graphics folio's drawing and text calls.

### Creating a Graphics Context

Before a task can use drawing and text calls, it must first create a graphics context data structure (known as a *GrafCon*), defined below:

```
10  /* Graphics Context structure */
    typedef struct GrafCon
    {
        Node gc;
15     Color gc_FGPen;
        Color gc_BGPen;
        Coord gc_PenX;
        Coord gc_PenY;
20     ulong gc_Flags;
    } GrafCon;
```

The *GrafCon* serves to keep track of the current status of the pen, an invisible cursor that moves through a bitmap as calls draw graphics primitives or render text. The pen has two colors: a foreground color and a background color, both specified as a 3DO RGB value in the low 15 bits of a 32-bit integer (the upper 17 bits are set to zero). The foreground color is stored in *gc\_FGPen*; the background color is stored in *gc\_BGPen*. The pen also has a position, specified in X and Y coordinates stored in *gc\_PenX* and *gcPenY*. These two values are each 32-bit integers that are read in either 16.16 or 17.15 format. <<<The field *gc\_Flags* isn't currently defined.>>>

The colors and the coordinates of the *GrafCon*'s pen are stored independently, and aren't connected to any specific bitmap or screen. When a task uses a drawing or text call, it specifies a bitmap where it

- 73 -

wishes to render, and then points to a GrafCon to use the values stored there. When the call executes, it often changes the GrafCon values when finished. For example, a line-drawing command uses a GrafCon's pen position to start the line, draws the line, and then  
5 changes the GrafCon's pen position to the position of the line's end. And a text rendering routine advances the pen position beyond the character just rendered.

A task can use as few or as many GrafCons as are  
10 useful. For example, one GrafCon can be used for rendering to multiple bitmaps; if so, the last-used GrafCon values in one bitmap become the first-used GrafCon values in a new bitmap when a call switches bitmaps but not GrafCons. A task may also create a  
15 separate GrafCon for each bitmap and switch to the appropriate GrafCon whenever it switches rendering to a new bitmap. Or a task may create more than once GrafCon for a single bitmap and use the multiple GrafCons to store multiple pen positions and colors  
20 within the bitmap, switching GrafCons whenever to switch pen states.

### Setting Pen Colors

When a GrafCon structure is first created, you can, of course, set it to whatever background and  
25 foreground pen colors you wish. To set new pen colors in the Grafcon, use these calls:

```
void SetFGPen( GrafCon *grafcon, Color color )
```

```
void SetBGPen( GrafCon *grafcon, Color color )
```

Each call accepts a pointer to the GrafCon and a  
30 15-bit 555 formatted color stored in the low 15 bits of a 32-bit integer. When executed, SetFGPen() changes the GrafCon's foreground pen color to the specified value; SetBGPen() changes the GrafCon's background pen color to the specified value.

- 74 -

If you have a 24-bit RGB color that you'd like to turn into a 15-bit RGB color value, use this convenience call:

```
int32 MakeRGB15( red, green, blue )
```

5 It accepts a red value, a green value, and a blue value (which you can supply from a 24-bit RGB value by breaking it into three 8-bit values). MakeRGB15() takes the lowest five bits from each value and combines them to create a 15-bit RGB value.

#### 10 **Setting Pen Position**

The GrafCon's stored pen position always specifies a point that is figured from the origin of whatever bitmap is specified by a graphics call. That position is often changed by the graphics folio after  
15 executing a drawing or text call. If you'd like to change the pen position without drawing or rendering text, use this call:

```
void MoveTo( GrafCon *grafcon, Coord x, Coord y )
```

20 MoveTo() accepts a pointer to the GrafCon whose pen position you want to change, as well as a 32-bit X and a 32-bit Y value. When executed, it writes the new pen position into the specified GrafCon so that the next call referring to that GrafCon uses the  
25 position as its starting pen position.

#### **Finding a Bitmap Within a Screen**

To specify a bitmap for rendering, you must know its item number. To get the item number, use this call:

```
30 item LocateBitmap( Item ScreenItem, long bitmapnumber )
```

This call accepts the item number of a screen in which you wish to find a bitmap, and the number of the

- 75 -

bitmap within that screen: 0 for the first bitmap within the screen, 1 for the second bitmap within the screen, and so forth. It returns the item number for the specified bitmap. If that bitmap doesn't exist (for example, if you specify bitmap 4 in a two bitmap screen), then the call returns a zero. If the call runs into any other problems, it returns a negative number (an error code).

### Drawing Graphics Primitives

10       Once a GrafCon is set up with proper pen colors and coordinates and you have the item number for a bitmap in which you wish to draw, you can use the graphics folio's drawing calls. The simplest is this call:

```
15       int32 WritePixel( Item bitmapItem, GrafCon
          *grafcon,
          Coord x, Coord y )
```

WritePixel() accepts the item number of the bitmap to which you want to render, and a pointer to the GrafCon whose pen values you want to use. It also accepts X and Y coordinates (each in a 32-bit integer). When executed, it writes the current foreground pen color into the pixel at the specified coordinates in the bitmap. Because this call has its own coordinates, it ignores the GrafCon's stored pen position. When the call is finished, it writes its own coordinates into the GrafCon to be used as the starting pen position for the next call.

To draw a line, use this call:

```
30       void DrawTo( Item bitmapItem, GrafCon *grafcon,
          Coord x, Coord y )
```

DrawTo() accepts the item number of the bitmap to which you want to render, a pointer to the GrafCon you

- 76 -

want to use, and X and Y coordinates to the end of the line. When executed, this call draws a line from the GrafCon's pen position to the position specified in its arguments. It uses the foreground pen color, and when finished, it writes the line end's coordinates in the GrafCon as the starting pen position for the next call.

Note that DrawTo() renders pixels at both the starting and ending locations in the line it draws.

To draw a filled rectangle in a bitmap, use this call:

```
int32 FillRect( Item bitmapItem, GrafCon
               *grafcon,
               Rect *boundary )
```

It, as other calls do, accepts a bitmap item number and a pointer to a GrafCon. It then accepts a pointer to a Rect data structure which defines the rectangle. Rect is defined as follows:

```
typedef struct Rect
{
  Coord rect_XLeft;
  Coord rect_YTop;
  Coord rect_XRight;
  Coord rect_YBottom;
} Rect;
```

The four coordinates (each a 32-bit integer) define the left, top, right, and bottom boundaries of the rectangle. The left and right boundaries are X coordinates; the top and bottom boundaries are Y coordinates.

Note that the Y values in the Rect structure should be even numbers to allow for the left/right pixel storage in VRAM. If they are odd numbers, the graphics folio rounds them up to the next higher even number.

- 77 -

**Finding a Pixel's Color and Address**

To find the color contents of a single pixel within a bitmap, use this call:

```
5      Color ReadPixel(  Item bitmapItem,  GrafCon
      *grafcon,
      Coord x, Coord Y )
```

This call accepts the item number of the bitmap where the pixel is located, a pointer to a GrafCon, and X and Y coordinates of a pixel within the bitmap.

10 When ReadPixel() executes, it returns the 3DO RGB color value of the specified pixel. It then changes the pen position of the GrafCon to the new X and Y coordinates.

To find the absolute address of a pixel within a screen (regardless of which bitmap it's in), use this call:

```
15      void *GetPixelAddress( Item screenItem, Coord x,
      Coord y)
```

The call accepts the item of the screen in which the pixel is located, and X and Y screen coordinates (figured from the screen's origin) of the pixel. When the call executes, it goes to the bitmap where the point specified by the coordinates is located, and finds the absolute address of the pixel there, which

20 it returns.

This call is particularly useful for cel projection when the cel's source data is a subrectangle extracted from a screen. This call can find the address necessary to set up the necessary

30 offsets in the preamble to the source data.

**Rendering Text**

To render text in a bitmap, the graphics folio's text calls depend on a font table, a set of 1-bit deep

- 78 -

patterns that define each character within a character set. <<<The structure of a font table hasn't been set in this release.>>> Within a font table, the pattern for each character is called a *character block*. A  
5 character block is a rectangle of 1-bit pixels that uses ones for pixels that are part of the character and zeros for pixels that are background to the character.

Text calls, like graphics calls, depend on a  
10 GrafCon for pen colors and pen position. Whenever a call renders text, it uses the foreground pen color for the character pixels and uses the background pen color for the background pixels. The pen position determines the location of the upper left corner of a  
15 character block.

### Setting a Font

A text rendering call uses the system's current font table whenever it renders characters to the screen. The current font is usually set to a default  
20 font, but if you want to set a different font, you may specify it with this call:

```
void SetCurrentFont( Font *font )
```

The call accepts a pointer to the font table you want to use and, after it is executed, sets the  
25 current font to the character set contained in the font table to which you pointed. Text rendering calls after this call use the new current font until you set another current font.

If you want to return to the system's original  
30 font, use this call:

```
void ResetCurrentFont( void )
```

It resets the font table pointer to the system's default font, and all text rendering calls after it use the default font (until and unless, of course, you

- 79 -

reset the current font once again). <<<In this  
release of Portfolio, if a task has set a new default  
font, it must *always* execute ResetCurrentFont() before  
it exits. In future releases, this will be taken care  
5 of automatically.>>>

If you're unsure of the font that is currently  
the current font, or if you want to find out the  
parameters of the current font, you can get a pointer  
to the current font's table by executing this call:

10 Font \*GetCurrentFont( void )

It returns a pointer to the default font table.

#### Placing Characters

Once you've set the font you want, you can place  
a single character in a bitmap with this call:

15 int32 DrawChar( GrafCon \*gcon, Item bitmapItem,  
uint32 character )

It accepts a pointer to a GrafCon and an item  
number for a bitmap to establish the graphics context  
and the bitmap to which you want to render. It also  
20 accepts an unsigned 32-bit integer that contains the  
code number of the character within the font table  
that you want to render. For English applications,  
this value will probably be a 7- or 8-bit ASCII code  
placed in the low-order bits of the integer (all other  
25 bits are set to zero). For international  
applications, this value will probably be a 16-bit  
Unicode number (or another standard).

When executed, DrawChar() renders the character  
block of the specified character into the bitmap using  
30 the pen position to set the upper left corner of the  
block, using the foreground pen color for the  
character bits, and using the background pen color for  
the background bits. After execution, it resets the  
GrafCon's pen position by adding the width of the

- 80 -

character just rendered to the pen's X coordinate. The call returns a zero if successful, and a negative number (an error code) if unsuccessful.

To place a string of 8-bit text, use this call:

```
5      int32 DrawText8( GrafCon *gcon, Item bitmapItem,
        uint8 *text )
```

It accepts a GrafCon and bitmap, and also accepts a pointer to a text string. The text string contains characters that are all defined in an 8-bit code such as ASCII, and are contained in memory one per byte.

10 When the call executes, it renders the characters specified by the string into the bitmap, using the GrafCon's background and foreground pen colors. The upper left corner of the first character starts at the

15 pen position stored in the GrafCon. When the string is rendered, the width of all the rendered characters is added to the X coordinate of the GrafCon's pen position.

#### Setting a Clipping Rectangle

20 Whenever the graphics folio projects cels or draws directly into a bitmap, it can write anywhere in the entire bitmap. If you wish to restrict cel projection and rendering to a subrectangle of the bitmap, you can do so with these calls:

```
25      int32 SetClipHeight( Item bitmapItem,  ulong
        clipHeight )

        int32 SetClipWidth( Item bitmapItem,  ulong
        clipWidth )
```

The two calls together set the dimensions of a

30 clipping rectangle within the specified bitmap. The first, SetClipHeight(), sets the number of rows within the clipping rectangle; the second, SetClipWidth(), sets the number of columns within the clipping

- 81 -

rectangle. Each call accepts the item number of a bitmap within which you wish to set a clipping rectangle, and a 32-bit unsigned integer containing the appropriate rectangle dimension in pixels.

5 Note that if the height or width of the clipping rectangle is equal to or larger than the height or width of the bitmap, then there is no clipping in that direction. Note also that if one of the dimensions is set without the other, the unset dimension is set to  
10 the full width or height of the bitmap.

When executed, these two calls create a clipping rectangle within a bitmap. Any cel projections or bitmap renderings (including text) that fall outside of the rectangle are clipped, and aren't written to  
15 the bitmap. The calls both return zero if the call was successful, or a negative number (an error code) if unsuccessful.

When a clipping rectangle's dimensions are set, the clipping rectangle's upper left corner is located  
20 in the upper left corner of the bitmap. To set the clipping rectangle in a different location within the bitmap, use this call:

```
int32 SetClipOrigin( Item bitmapItem, Coord x,  
Coord y )
```

25 This call accepts the item number of the bitmap in which you want to move the clipping rectangle; it also accepts the X and Y coordinates of the point within that bitmap where you want to move the clipping rectangle's origin.

30 When SetClipOrigin() executes, it moves the clipping rectangle so that its origin falls on the specified point. It returns a zero if successful, or a negative number (an error code) if unsuccessful.

Note that if you move a clipping rectangle so  
35 that any of its boundaries fall beyond the bitmap

- 82 -

boundaries, it is an error. It's wise, therefore, when you're reducing a clipping rectangle size to first set the height and width and then set the origin. If you're enlarging the clipping rectangle, you should first set the origin to a new (and safe location), and then set the height and width. And if you don't know what size the current clipping rectangle is or where it's located, you should first set the origin to 0, 0 then set the new height and width and only then reset the origin where you want it.

#### **REFRESHING BACKGROUNDS WITH SPORT TRANSFERS**

SPORT transfers take advantage of the high speed SPORT bus to copy one or more pages of VRAM to other pages of VRAM. Because a SPORT transfer always takes place during the vertical blank, it's a perfect method for refreshing a frame buffer background between cel projections. To set up background refreshment with SPORT, you must first know the set of VRAM pages used to store the bitmap (or bitmaps) you wish to refresh. You must then create and store a background image in a bitmap that won't be written into (it doesn't have to be part of a screen). Finally, you must make sure that all these bitmaps reside within the same VRAM bank so that SPORT will work among them. The tag args of the CreateScreenGroup() call can help you make sure that bitmaps are all allocated within the same bank.

Consider an example: A double-buffered screen group has two screens; each screen has a single bitmap. The two screen bitmaps are stored in the same bank of VRAM; each starts on a page boundary and takes nine and a half pages of VRAM. A third non-screen bitmap is created in nine and a half pages of VRAM. All the bitmaps reside in the same VRAM bank.

- 83 -

Now if you want to project moving cels on a static background--say, for example, crawling centipedes on a background of mushrooms--you store the mushroom background in the third bitmap. You then use  
5 a SPORT transfer to copy the mushroom background to the non-displayed screen in the screen group, which presents a clean background. You then project the centipede cels where they should be for that particular frame. When the screens are swapped for  
10 the next frame, you use SPORT to copy the clean background into the second screen, which is no longer displayed, and then project the centipede cels in a new position for the next frame. Each SPORT transfer removes projected cel images from the background so  
15 they won't linger into a later frame.

Because the SPORT bus is a device, all SPORT calls require an IOReq to communicate to the SPORT device. The graphics folio provides a convenience call to create a special IOReq for that purpose, which  
20 you can use in SPORT calls.

#### **Creating an IOReq for the Sport Device**

To create an IOReq to use with the SPORT device, use this call:

```
Item GetVRAMIOReq( void )
```

25 This call requires no argument and, when executed, creates an IOReq item for use with the SPORT bus. It returns the item number of that IOReq, which you should store for other SPORT calls. If unsuccessful, it returns a negative value (an error  
30 code).

#### **Copying VRAM Pages**

If your bitmaps are set up to fit within a known set of VRAM pages, you can use this call to copy the

- 84 -

range of pages containing one bitmap into a second range of pages containing another bitmap:

```
Err CopyVRAMPages( item ioreq, void *dest, void
                  *src, uint32 numPages, uint32 mask )
```

5           The call accepts the item number of the SPORT  
IOReq, a pointer to the beginning address of the  
destination bitmap, a pointer to the beginning address  
of the destination bitmap, and the number of VRAM  
pages you wish to copy from the source to the  
10 destination. It also accepts a 32-bit mask.

          When CopyVRAMPages() executes, it waits until the  
next vertical blank to read the specified number of  
VRAM pages starting at the source address, and then  
copies those pages into the same number of VRAM pages  
15 starting at the destination address. The 32-bit mask  
determines which pixels within the source are copied;  
it provides a pattern of 32 ones and zeros that is  
repeated and applied consecutively to rows of pixels  
in the source pages. Only pixels coinciding with a  
20 one in the mask are copied to the destination pages.  
Pixels coinciding with a zero in the mask aren't  
copied.

          Note that the source and destination pointers you  
use will probably fall within a VRAM page and not  
25 directly on a page border. If so, CopyVRAMPages()  
automatically finds the starting page addresses of the  
pages you point to, and uses those addresses for  
copying VRAM pages.

#### **Cloning a Single VRAM Page**

30           It is useful sometimes to be able to clone a  
single VRAM page to many different destination pages.  
If, for example, a background bitmap contains a  
repeated pattern, there's no need to use many pages to  
store it--a single page can store the pattern, and it

- 85 -

can be duplicated as many times as necessary to fill a full bitmap. To clone a single page, use this call:

```
Err CloneVRAMPages( Item ioreq, void *dest, void
                    *src, uint32 numPages, uint32 mask )
```

5           Like CopyVRAMPages(), it accepts an ioreq item number and pointers to source and destination VRAM addresses (usually the beginnings of bitmaps). It also accepts the number of destination pages to which the single source page is cloned, and a 32-bit mask.

10           When CloneVRAMPages() executes, it waits for the next vertical blank to read the specified source VRAM page, apply the 32-bit mask to it, and then copy the results as many times as necessary to fill all the specified destination VRAM pages.

#### 15   **Setting VRAM Pages to a Single Color or Pattern**

          If a bitmap background is all one color, you can save quite a bit of VRAM by setting a single color value instead of creating a full backup bitmap or VRAM page. You then use FlashWrite to copy that value into  
20   full pages of VRAM with this call:

```
Err SetVRAMPages( Item ioreq, void *dest, int32
                  value, int32 numpages, int32 mask )
```

          The call accepts an ioreq item number. It also accepts a pointer to a VRAM destination and the number  
25   of pages, starting at that destination, to which it will copy the color value. It accepts a 32-bit color value that is the 15-bit 3DO RGB color value with a sixteenth high-order bit of zero added, then duplicated to fill 32 bits. It also accepts a 32-bit  
30   mask that works here just as it does in the SPORT calls.

          When SetVRAMPages() executes, it waits until the next vertical blank, and then copies the specified

- 86 -

color value into the specified VRAM pages using the copy mask to determine which pixels in the source pages get the copied color value and which pixels do not.

5           To create the color value used with SetVRAMPages(), use this call:

```
int32 MakeRGB15Pair( red, green, blue )
```

10           It accepts a red, green, and blue value, combines the low five bits of each value, to create a single 15-bit RGB value, then duplicates it to create a 32-bit color value accepted by SetVRAMPages(). It returns the 32-bit color value.

#### Deferred SPORT Calls

15           Two of the last SPORT calls--CopyVRAMPages() and CloneVRAMPages()--all put the calling task in wait state while they execute, and only return the task to active state once the SPORT device has processed the IOReq and completed the operation. If you'd like to perform the same operations without waiting for the operation to complete (for asynchronous SPORT I/O), you can use "deferred" versions of the same calls:

```
Err CopyVRAMPagesDefer( Item ioreq, void *dest,
void
*src, uint32 numPages, uint32 mask )
```

25           Err CloneVRAMPagesDefer( Item ioreq, void \*dest,
void \*src, uint32 numPages, uint32 mask )

```
Err SetVRAMPagesDefer( Item ioreq, void *dest,
int32
value, int 32 numpages, int32 mask )
```

30           These calls all accept the same arguments as their nondeferred counterparts, but don't put the calling task in wait state while they execute, so the task is free to continue execution while the SPORT

- 87 -

device reads the IOReq and performs the requested operation.

(Note the SetVRAMPages() doesn't put its calling task in wait state, so it executes exactly the same as SetVRAMPagesDefer(), which is included only to make a complete set of deferred SPORT calls.

#### DISPLAY TIMING CALLS

If you have other task activities you want to coordinate with the frame display, you can use the timer device to inform the task when a vertical blank occurs. The task can enter wait state until it receives notice of the vertical blank, or it can continue while it waits.

#### Getting a VBL IOReq

To use VBL timing calls, a task must first have an IOReq to communicate with the timer. To get one, use this convenience call:

Item GetVBLIOReq( void )

It accepts no arguments, and when it executes, it creates an IOReq for the timer. It returns the item number of that IOReq if successful, or a negative value (an error code) if unsuccessful. Save the item number for use with the VBL timing calls.

#### Waiting For a VBL Frame

Once a task has a VBL IOReq, it can call on the timer to wait for a vertical blank. To do so, it uses this call:

Err WaitVBL( Item ioreq, uint32 numfields )

It accepts the item number of the VBL IOReq and the number of vertical blank fields the task should wait before becoming active again. It returns a zero

- 88 -

if successful, and a negative value (an error code) if unsuccessful.

To allow a task to continue execution while the timer processes the IOReq sent to it, use this call:

5       Err WaitVBLDefer( Item ioreq, uint32 numfields )

It accepts the same arguments as WaitVBL(), but-- when executed--allows the task to continue execution while the IOReq is outstanding. If the task wants to be notified of the timing call's completion, it should use the WaitIO() call.

10

#### CONTROLLING PIXEL INTERPOLATION

The display generator, in its default state, practices full pixel interpolation for all 320x240 pixels it receives from a screen. If you'd like to turn off interpolation for the "crispy pixels" look within a screen, you can use these two calls:

15

int32 DisableHAVG( Item screenItem )

int32 DisableVAVG( Item screenItem )

The first call disables horizontal interpolation for the specified screen; the second call disables vertical interpolation for the specified screen. If either call is successful, it returns a zero. If unsuccessful, it returns a negative number (an error code).

20

To turn interpolation back on, use these two calls:

25

int32 EnableHAVG( Item screenItem )

int32 EnableVAVG( Item screenItem )

The first call enables horizontal interpolation for the specified screen; the second call enables vertical interpolation for the specified screen. If either call is successful, it returns a zero. If unsuccessful, it returns a negative number (an error code).

30

- 89 -

**PRIMARY DATA STRUCTURES****The Graphics Context (GrafCon) Data Structure**

```

/* Graphics Context structure */
typedef struct GrafCon
5      {
      Node gc;
      Color gc_FGPen;
      Color gc_BGPen;
      Coord gc_PenX;
10     Coord gc_PenY;
      ulong gc_Flags;
      } GrafCon;

```

**The Rect Data Structure**

```

typedef struct Rect
15     {
      Coord rect_XLeft;
      Coord rect_YTop;
      Coord rect_XRight;
      Coord rect_YBottom;
20     } Rect;

```

**PROCEDURE CALLS**

The following graphics folio calls control bitmaps, screens, and the display generator. They also write to bitmaps and frame buffers.

**25 Screen Calls**

```

Item CreateScreenGroup( item *screenItemArray,
      TagArg *tagArgs )

int32 AddScreenGroup( Item screenGroup, TagArg
      *targs )

30 int32 DisplayScreen( Item ScreenItem0, Item
      ScreenItem1 )

int32 MoveScreenGroup( Item screenGroup, Coord x,
      Coord y, level )

int32 RemoveScreenGroup( Item screenGroup )

```

**35 VDL Calls**

```

int32 SubmitVDL( VDLEntry *vdlDataPtr )

```

- 90 -

```
long ModifyVDL( item IVDL, long linenumber, long
               *Targs )
```

```
int32 Set VDL( Item screenItem, Item vdlItem )
```

### Screen Color Calls

```
5      int32 MakeCLUTColorEntry( index, red, green, blue
                               )
      int32 MakeCLUTRedEntry( index, red )
      int32 MakeCLUTGreenEntry( index, blue )
      int32 Make CLUTBlueEntry( index, blue )
10     int32 SetScreenColor( Item screenItem, int32
                           colorEntry )
      int32 SetScreenColors( Item screenItem, int32
                             *entries, int32 count )
      RGB888 ReadScreenColor( ulong index )
15     int32 ResetScreenColors( Item screenItem )
```

### Drawing Calls

```
      void SetFGPen( GrafCon *grafcon, Color color )
      void SetBGPen( GrafCon *grafcon, Color color )
      int32 MakeRGB15( red, green, blue )
20     void MoveTo( GrafCon *grafcon, Coord x, Coord y
                 )
      Item LocateBitmap( Item ScreenItem, long
                        bitmapnumber )
25     int32 WritePixel( Item bitmapItem, GrafCon
                       *grafcon,
                       Coord x, Coord y )
      void DrawTo( Item bitmapItem, GrafCon *grafcon,
                  Coord x, Coord y )
30     void FillRect( Item bitmapItem, GrafCon *grafcon,
                    Coord x, Coord y )
```

- 91 -

```
Color ReadPixel( Item bitmapItem, GrafCon
*grafcon,
  Coord x, Coord Y )
```

```
5 void *GetPixelAddress( Item screenItem, Coord x,
  Coord y )
```

**Text Calls**

```
void SetCurrentFont( Font *font )
```

```
void ResetCurrentFont( void )
```

```
Font *GetCurrentFont( void )
```

```
10 int32 DrawChar( GrafCon *gcon, Item bitmapItem,
  uint32 character )
```

```
int32 DrawText8( GrafCon *gcon, item bitmapItem,
  uint8 *text )
```

**Clipping Calls**

```
15 int32 SetClipHeight( Item bitmapItem, ulong
  clipHeight )
```

```
int32 SetClipWidth( Item bitmapItem, ulong
  clipWidth )
```

```
20 int32 SetClipOrigin( Item bitmapItem, Coord x,
  Coord y )
```

**Bitmap Copying Calls**

```
void CopyVRAMPages( void *dest, void *src, ulong
  numPages, ulong mask )
```

```
25 void CloneVRAMPages( void *dest, void *src, ulong
  numPages, ulong mask )
```

```
void SetVRAMPages( void *dest, ulong value, ulong
  numPages, ulong mask )
```

```
int32 MakeRGB15Pair( red, green, blue )
```

**SlipStream and GenLock Calls**

```
30 Display Timing Calls
```

```
void WaitVBL()
```

- 92 -

**Interpolation Calls**

```
int32 DisableHAVG( Item screenItem )
int32 DisableVAVG( Item screenItem )
int32 EnableHAVG( Item screenItem )
5 int32 EnableVAVG( Item screenItem )
```

-----

Source-Code Section

NOTICE: The below C language source code listings are subject to copyright claims with the exception of the waiver provided in the initial section of this document entitled "2a. Copyright Claims to Disclosed Code".

By way of introduction, the dot-h (.h) files are C language include files. The CreateScreenGroup() function creates a data structure called a screen group. A screen group is comprised of plural screens each having an item number attached to it. Each screen has one VDL and one or more bitmaps associated to it. A VDL includes a pointer to an image buffer that is to be displayed. A bitmap includes an independent pointer which is initially set to point to the same image buffer as the corresponding VDL. The bitmap pointer, together with height and width variables of the bitmap, defines the area into which the spryte engines will draw. The function ProofVDLEntry() proofs submitted, VDL's and returns an error code if there is a problem. The CreateScreenGroup() function links through an interface to another function internalCreateScreenGroup() which then links to

- 93 -

```
realCreateScreenGroup to generate the VDL for each
screen. Corresponding bitmaps are generated by
internalCreateBitmap(). The function
internalCreateGrafItem() links the item numbers of the
5 VDL and bitmaps to the item number of a common screen.
  //
  //
  //
  //
10 //
  //
  //
  //
  //
15 //
```

```

/* This macro allows you to turn the absolute address of an object
35 * into the sort of relative address needed by the cel engine. The
* first argument is the absolute address of the field to receive the
* relative address, and the second argument is the absolute
* address of the object to be referenced.
* For instance, to create a relative pointer to a "next cel" you
40 * would use these arguments:
* MakeCCBRelative( &cel->ccb_NextPtr, &NextCel );

```

- 103 -

```

* To make sure your cel indicates it has a relative pointer to the
* next cel, you might want to explicitly clear the control flag:
*   ClearFlag( cel->ccb_Flags, CCB_NPABS );

 * screen and all its associated data structures.
 *
5  * The ScreenInfo ends with an instance of the BitmapInfo
 * structure.
 * In actuality, there can be any number of BitmapInfo structures at
 * the end of the ScreenInfo structure. In the simple case, which
 * almost everyone will use, a screen will be comprised of a single
10 * bitmap.
 * To simplify references to the ScreenInfo fields, the ScreenInfo
 * structure is defined as having a single instance of a BitmapInfo
 * structure. Furthermore, to simplify allocation of and referencing
 * to ScreenInfo structures with more than a single bitmap, the
15 * ScreenInfo2 and ScreenInfo3 structures are defined to describe
 * screens that have two and three bitmaps. These are defined for
 * your convenience.
 *
 * The InitScreenInfo() call presumes that your ScreenInfo argument
20 * points to a ScreenInfo structure with the correct number of
 * BitmapInfo fields at the end of it.
 *
 * Hmm:
 * ScreenInfo ScreenInfos[2];
25 * ScreenInfo *ScreenInfoPtrs[2] = {&ScreenInfos[0],
 * &ScreenInfos[1]};
 * CreateScreenGroup( ScreenInfoPtrs, TagArgs );
 * DrawCels( ScreenInfos[ScreenSelect].si_BitmapInfo.bi_Item,
 * &Cel );
30 * DisplayScreen( ScreenInfos[ScreenSelect].si_Item, 0 );

```

The above disclosure is to be taken as illustrative of the invention, not as limiting its scope or spirit. Numerous

20 modifications and variations will become apparent to those skilled in the art after studying the above disclosure. For example, the invention is not restricted to RGB formats. Other digital formats such as YCC, or Composite Video Broadcast Standard (CVBS), can also be used. For the sake of simplification, an RGB format was

25 assumed above.

Given the above disclosure of general concepts and specific embodiments, the scope of protection sought is to be defined by the claims appended hereto.

CLAIMS

What is claimed is:

[Note: Bracketed text is provided as an aid for readability and for finding corresponding elements in the specification. The bracketed text should be deleted in the final version of the claims.]

1. A configurable imaging system comprising:
  - (a) a memory unit [120] for storing low-resolution pixel data of adjacent, low-resolution scan lines in respectively addressable memory locations;
  - 5 (b) configurable CLUT means [451,452,484] for extracting from the memory unit, image data defined at N bits-per-pixel and for producing therefrom enhanced image data signals defined at M bits-per-pixel, where  $M > N$ ;
  - (c) configurable video display drive means [105] for  
10 translating the enhanced image data signals produced by the CLUT means [451,452,484] into video signals compatible with a target video display unit [160]; and
  - (d) configuration management means, operatively coupled to  
15 the CLUT means [451,452,484] and to the video display drive means [105], for outputting configuration instructions to the CLUT means [451,452,484] and the video display drive means [105] and thereby respectively configuring the CLUT means [451,452,484] and the video display drive means [105] in accordance with predefined configuration criteria;
  - 20 wherein the configuration management means includes initializing means for initializing the configuration of the display drive means [105] in accordance with predefined configuration criteria during a system initializing phase; and
  - wherein the configuration management means further includes

25 output filtering means for filtering the configuration instructions  
output by the configuration management means after the system  
initializing phase and for removing from the output configuration  
instructions, instructions that seek to reconfigure the display drive  
means [105] after the system initializing phase.

2. A configurable imaging system comprising:

(a) a memory unit [120] for storing low-resolution pixel data  
of adjacent, low-resolution scan lines in respectively addressable  
memory locations;

5 (b) configurable interpolation means [459] for extracting from  
the memory unit, image data defined at a resolution of n-by-m pixels  
and for producing therefrom enhanced image data signals defining a  
resolution of N-by-M pixels, where the number of pixels in the N-by-  
M image is substantially greater than the number of pixels in the n-  
10 by-m image;

(c) configurable video display drive means [105] for  
translating the enhanced image data signals produced by the  
interpolation means [459] into video signals compatible with a  
target video display unit [160]; and

15 (d) configuration management means, operatively coupled to  
the interpolation means [459] and to the video display drive means  
[105], for outputting configuration instructions to the interpolation  
means [459] and to the video display drive means [105] and thereby  
respectively configuring the interpolation means [459] and the video  
20 display drive means [105] in accordance with predefined  
configuration criteria;

wherein the configuration management means includes  
initializing means for initializing the configuration of the display drive  
means [105] in accordance with predefined configuration criteria

25 during a system initializing phase; and  
wherein the configuration management means further includes  
output filtering means for filtering the configuration instructions  
output by the configuration management means after the system  
initializing phase and for removing from the output configuration  
30 instructions, instructions that seek to reconfigure the display drive  
means [105] after the system initializing phase.

3. A method for downloading a list of display control  
words from system memory [120] to a configurable image-  
enhancing and display subsystem [150], said method comprising the  
steps of:

- 5 (a) defining in a first region [215.0] of the system memory  
[120], a first control word [311] having a ListLen field, where the  
first control word [311] is to be processed before a corresponding  
first image line [125.0] is displayed and where the ListLen field  
indicates a number of additional control words [312-315] that are to  
10 optionally follow the first control word [311] before the display of  
the corresponding first image line, said first region [215.0] being a  
region from which control words can be downloaded to the image-  
enhancing and display subsystem [150] prior to the display of the  
corresponding first image line [125.0];
- 15 (b) defining in said first memory region [215.0], a second  
control word [312] following the first control word [311], where the  
second control word [312] includes a pointer to a memory buffer  
[125.0] containing at least the to-be displayed first image line;
- (c) defining in said first memory region [215.0], a third control  
20 word [313] following the second control word [312]; and
- (d) defining in said first memory region [215.0], a fourth  
control word [314] following the third control word [313], where

the fourth control word [314] includes a pointer to a next memory region [215.1] having control words to be optionally executed prior to display of another image line, the display of the other image line following the display of said first image line [125.0].

4. The download method of Claim 3 wherein the third control word [313] includes a pointer to a memory buffer [125.0] containing a previous image line to be used for enhancing the display of the at least first image line.

5. The download method of Claim 3 wherein the first control word [311] further includes a NexVLCBr field indicating whether the pointer of the fourth control word [314] is relative or absolute.

6. A method for creating a displayable, animateable, image structure [250] within a memory [120] of an image display system [100] having a first transfer subsystem [150] for transferring image data from the memory to an image integration means [160,170] and a second transfer system [109/110] for moving new image data into a region of said memory, the method comprising the steps of:

(a) defining in a first region [255,265] of the system memory [120], a first image buffer containing one or more lines of bit-mapped image data that can be displayed by way of said first transfer subsystem [150];

(b) defining in a second region [251,261] of the system memory [120], a first video display control block [252,262] having a pointer [253,263] pointing to the first image buffer [255,265] and further having first control words [311-314] for causing the first transfer subsystem [150] to transfer the image data of the first

image buffer [255,265] to the image integration means [160,170];  
and

(c) defining in a third region [256,266] of the system memory [120], a first cel animation control block also having a pointer [257] pointing to the first image buffer [255,265], the first cel animation control block [256,266] further having cel animation control words [258-259] for causing the second transfer system [109/110] to move new image data into a region of said first image buffer [255,265].

7. The image structure creation method of Claim 6 further comprising the steps of:

(d) defining in a fourth region [285] of the system memory [120], a second image buffer containing one or more lines of bit-mapped image data that can be displayed by way of said first transfer subsystem [150];

(e) defining in a fifth region [261] of the system memory [120], a second video display control block [264] having a pointer [283] pointing to the second image buffer [285] and further having second control words [311-314] for causing the first transfer subsystem [150] to transfer the image data of the second image buffer [285] to the image integration means [160,170]; and

(f) defining in a sixth region [286] of the system memory [120], a second cel animation control block also having a pointer [257] pointing to the second image buffer [285], the second cel animation control block [286] further having cel animation control words [258-259] for causing the second transfer system [109/110] to move new image data into a region of said second image buffer [285].

8. The image structure creation method of Claim 7 further comprising the step of:

linking [269] the first video display control block [262] to the second video display control block [264] so as to cause the first transfer subsystem [150] to transfer the image data of the first and second image buffers [265,285] to the image integration means [160,170] one after the next.

9. The image structure creation method of Claim 8 further comprising the steps of:

(g) defining in a seventh region [275] of the system memory [120], a third image buffer containing one or more lines of bit-mapped image data that can be displayed by way of said first transfer subsystem [150];

(h) defining in an eighth region [271] of the system memory [120], a third video display control block [272] having a pointer [273] pointing to the third image buffer [285] and further having second control words [311-314] for causing the first transfer subsystem [150] to transfer the image data of the third image buffer [275] to the image integration means [160,170]; and

(i) defining in a ninth region [276] of the system memory [120], a third cel animation control block also having a pointer [257] pointing to the third image buffer [275], the third cel animation control block [276] further having cel animation control words [258-259] for causing the second transfer system [109/110] to move new image data into a region of said third image buffer [275].

10. An image draw and display system comprising:

(a) a memory unit [120];

(b) image buffer defining means for defining in the memory

unit, an image buffer [255] containing displayable image data;

5 (c) display pointing means for defining in the memory unit, a display pointer [253] pointing to the image buffer [255], said display pointer [253] being accessible by an image display engine [115'] that transfers the pointed-to image data of the image buffer [255] to a image integration means [160,170]; and

10 (d) animation-destination pointing means for defining in the memory unit, an animation-destination pointer [257] also pointing the image buffer [255], said animation-destination pointer [257] being accessible by one or more spryte-rendering engines [109a,b] that write new image data into a portion of the image buffer [255] pointed-to by the animation-destination pointer [257];

15 wherein the image buffer [255], the display pointer [253], and the animation-destination pointer [257] are all defined within the memory unit [120] at the same time so as to enable independent display of the displayable image data pointed to by the display  
20 pointer [253], and independent rendition of new image data into the portion of the image buffer [255] pointed-to by the animation-destination pointer [257].

11. A multi-screen buffering system comprising:

(a) a memory unit [120];

(b) image buffer defining means for defining in the memory unit, at least first through third image buffers [265,275,285] each  
5 containing displayable image data;

(c) display pointing means for defining in the memory unit, at least first through third display pointers [263,273,283] respectively pointing to the at least first through third image buffers [265,275,285], said at least first through third display pointers  
10 [263,273,283] being accessible by an image display engine [115']

that transfers the pointed-to image data of an activated one or more of the at least first through third image buffers [265,275,285] to a image integration means [160,170];

15 (d) animation-destination pointing means for defining in the memory unit, at least first through third animation-destination pointers [266,276,286] also respectively pointing to the at least first through third image buffers [265,275,285], said at least first through third animation-destination pointers [266,276,286] being accessible by one or more spryte-rendering engines [109a,b] that  
20 write new image data into portions of the corresponding at least first through third image buffers [265,275,285] when a corresponding one or more of the at least first through third animation-destination pointers [266,276,286] are queued onto an animation control queue; and

25 (e) activation and queue control means for:

(e.11) in a first instance activating a first subset [263,283] of said display pointers while deactivating a second subset [275] of said display pointers, and

30 (e.12) in the same first instance queuing the animation-destination pointer of at least one image buffer [285] in the first subset whose display pointer is activated and de-queuing the animation-destination pointer of at least one other image buffer [265] in the first subset whose display pointer is activated, and

35 (e.13) in the same first instance queuing the animation-destination pointer of at least one image buffer [275] in the second subset whose display pointer is de-activated.

12. The multi-screen buffering system of Claim 11 wherein the activation and queue control means is further for:

(e.21) in a second instance activating a third subset

[273,283'] of said display pointers while deactivating a fourth  
5 subset [265] of said display pointers, and

(e.22) in the same second instance queuing the animation-  
destination pointer of at least one image buffer [285] in the third  
subset whose display pointer is activated and de-queuing the  
animation-destination pointer of at least one other image buffer  
10 [275] in the third subset whose display pointer is activated, and  
(e.23) in the same second instance queuing the animation-  
destination pointer of at least one image buffer [265] in the fourth  
subset whose display pointer is de-activated.

13. A configurable imaging system comprising:

(a) a memory unit [120] for storing low-resolution pixel data  
of adjacent, low-resolution scan lines in respectively addressable  
memory locations;

5 (b) configurable CLUT means [451,452,484] for extracting  
from the memory unit, image data defined at N bits-per-pixel and for  
producing therefrom enhanced image data signals defined at M bits-  
per-pixel, where  $M > N$ ;

(c) configurable interpolation means [459] for extracting from  
10 the memory unit, image data defined at a resolution of n-by-m pixels  
and for producing therefrom enhanced image data signals defining a  
resolution of N-by-M pixels, where the number of pixels in the N-by-  
M image is substantially greater than the number of pixels in the n-  
by-m image; and

15 (d) configuration management means, operatively coupled to  
the CLUT means [451,452,484] and to the interpolation means  
[459], for outputting configuration instructions to the CLUT means  
[451,452,484] and to the interpolation means [459], and thereby  
respectively configuring the CLUT means [451,452,484] and the

- 20 configurable interpolation means [459] in accordance with  
predefined configuration criteria;  
wherein the configuration management means includes  
initializing means for initializing the configuration of the interpolation  
means [459] in accordance with predefined configuration criteria  
25 during a system initializing phase; and  
wherein the configuration management means further includes  
output filtering means for filtering the configuration instructions  
output by the configuration management means after the system  
initializing phase and for removing from the output configuration  
30 instructions, instructions that seek to reconfigure the interpolation  
means [459] after the system initializing phase.

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US94/12521**Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)**

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1.  Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
  
2.  Claims Nos.:  
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
  
3.  Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1.  As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2.  As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3.  As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
  
4.  No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- The additional search fees were accompanied by the applicant's protest.  
 No protest accompanied the payment of additional search fees.

**BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING**

This ISA found multiple inventions as follows:

I. Claims 1, 2 and 13, drawn to a configuration management system by using CLUT, classified in Class 345, subclass 199.

II. Claims 3-5, drawn to a system for downloading the display control words in a memory system, classified in Class 345, subclass 185.

III. Claims 6-12, drawn to an animation creation system, classified in Class 395, subclass 152.

Following is a further Lack of Unity in Group III:

I. Claims 6-9, drawn to a system for creating an animation by defining different regions in the system memory and having pointers for pointing the image buffers, classified in Class 395, subclass 152.

II. Claim 10-12, drawn to a system for creating an animation by using animation-destination pointing means, classified in Class 395, subclass 152.

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

The inventions listed as Groups I, II and III do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons:

Inventions I, II and III are related as subcombinations disclosed as usable together in a single combination. The four groups define different devices or subcombinations that are usable together but which do not share the same special technical features. For instance Group I discloses a configuration management system which employs structure different from the system for downloading a memory system of group II and/or the different animation systems of group III.
